1. Introduction

Let $E/\mathbb{Q}$ be a modular elliptic curve of conductor $N$, and let $p$ be a prime of split multiplicative reduction for $E$. Write $\mathbb{C}_p$ for a fixed completion of an algebraic closure of $\mathbb{Q}_p$. Tate’s theory of $p$-adic uniformization of elliptic curves yields a rigid-analytic, $\text{Gal}(\mathbb{C}_p/\mathbb{Q}_p)$-equivariant uniformization of the $\mathbb{C}_p$-points of $E$:

$$0 \to q^\mathbb{Z} \to \mathbb{C}_p^\times \xrightarrow{\Phi_{\text{Tate}}} E(\mathbb{C}_p) \to 0,$$

where $q \in p\mathbb{Z}_p$ is the $p$-adic period of $E$.

Mazur, Tate, and Teitelbaum conjectured in [MTT] that the cyclotomic $p$-adic $L$-function of $E/\mathbb{Q}$ vanishes at the central point to order one greater than that of its classical counterpart. Furthermore, they proposed a formula for the leading coefficient of such a $p$-adic $L$-function. In the special case where the analytic rank of $E(\mathbb{Q})$ is zero, they predicted that the ratio of the special value of the first derivative of the cyclotomic $p$-adic $L$-function and the algebraic part of the special value of the complex $L$-function of $E/\mathbb{Q}$ is equal to the quantity

$$\frac{\log p(q)}{\text{ord}_p(q)}$$

(where \( \log_p \) is Iwasawa’s cyclotomic logarithm), which is defined purely in terms of the \( p \)-adic uniformization of \( E \). Greenberg and Stevens [GS] gave a proof of this special case. See also the work of Boichut [Boi] in the case of analytic rank one.

The article [BD1] formulates an analogue of the conjectures of [MTT] in which the cyclotomic \( \mathbb{Z}_p \)-extension of \( \mathbb{Q} \) is replaced by the anticyclotomic \( \mathbb{Z}_p \)-extension of an imaginary quadratic field \( K \). When \( p \) is split in \( K \) and the sign of the functional equation of \( L(E/K,s) \) is \(+1\), this conjecture relates the first derivative of the anticyclotomic \( p \)-adic \( L \)-function of \( E \) to the anticyclotomic logarithm of the \( p \)-adic period of \( E \). The present paper supplies a proof of this conjecture. Our proof is based on the theory of \( p \)-adic uniformization of Shimura curves.

More precisely, assume that \( K \) is an imaginary quadratic field with \( \text{disc}(K), N = 1 \) such that

(i) \( p \) is split in \( K \);

(ii) \( E \) is semistable at the rational primes that divide \( N \) and are inert in \( K \);

(iii) the number of these rational primes is odd.

The complex \( L \)-function \( L(E/K,s) \) of \( E \) over \( K \) has a functional equation and an analytic continuation to the whole complex plane. Under our assumptions, the sign of the functional equation of \( L(E/K,s) \) is \(+1\) (cf. [GZ, p. 71]), and hence \( L(E/K,s) \) vanishes to even order at \( s = 1 \).

Fix a positive integer \( c \) prime to \( N \), and let \( \mathcal{O} \) be the order of \( K \) of conductor \( c \). Let \( H_0 \) be the ring class field of \( K \) of conductor \( cp^n \), with \( n \geq 0 \), and let \( H_\infty \) be the union of the \( H_n \). By class field theory, the Galois group \( \text{Gal}(H_\infty/H_0) \) is identified with \( \mathcal{O}_K^\times \otimes \mathbb{Z}_p^\times \simeq \mathbb{Z}_p \times \mathbb{Z}/((p-1)/u)\mathbb{Z} \), with \( u := (1/2)\#\mathcal{O}_K^\times \). Moreover, \( \text{Gal}(H_0/K) \) is identified with the Picard group \( \text{Pic}(\mathcal{O}) \). Set

\[
G_n := \text{Gal}(H_n/K), \quad G_\infty := \text{Gal}(H_\infty/K).
\]

Thus, \( G_\infty \) is isomorphic to the product of \( \mathbb{Z}_p \) by a finite abelian group. Choose a prime \( p \) of \( K \) above \( p \). Identify \( \mathbb{Q}_p \) with \( \mathbb{Q} \) and let

\[
\text{rec}_p : \mathbb{Q}_p^\times \to G_\infty
\]

be the reciprocity map of local class field theory. Define the integral completed group ring of \( G_\infty \) to be

\[
\mathbb{Z}[[G_\infty]] := \lim_{\leftarrow n} \mathbb{Z}[G_n],
\]

where the inverse limit is taken with respect to the natural projections of group rings.

In Section 3, we recall the construction explained in [BD1, Sec. 2.7] of an element

\[
\mathcal{L}_p(E/K) \in \mathbb{Z}[[G_\infty]]
\]

attached to \( (E, H_\infty/K) \), which interpolates the special values \( L(E/K, \chi, 1) \) of \( L(E/K,s) \) twisted by finite-order characters of \( G_\infty \). The construction of this \( p \)-adic \( L \)-function is based on the ideas of Gross [Gr] and a generalization due to Daghigh [Dag]. We show that \( \mathcal{L}_p(E/K) \) belongs to the augmentation ideal \( I \) of \( \mathbb{Z}[[G_\infty]] \). Let
\[ \mathcal{L}'_p(E/K) \] be the natural image of \( \mathcal{L}_p(E/K) \) in \( I/I^2 = G_\infty \). The element \( \mathcal{L}'_p(E/K) \) should be viewed as the first derivative of \( \mathcal{L}_p(E/K) \) at the central point.

Let \( f = \sum_{n \geq 1} a_n q^n \) be the newform attached to \( E \), and let

\[
\Omega_f := 4\pi^2 \int \int_{\mathfrak{H}/\Gamma_0(N)} |f(\tau)|^2 d\tau \wedge i d\bar{\tau}
\]

be the Petersson inner product of \( f \) with itself. We assume that \( E \) is the strong Weil curve for the Shimura curve parametrization defined in Section 4. Let \( d := \text{disc}(\mathcal{O}) \), and let \( n_f \) be the positive integer defined later in this introduction and specified further in Section 2. Our main result (stated in a special case: see Theorem 6.4 for the general statement) is the following.

**Theorem 1.1.** Suppose that \( c = 1 \). The equality (up to sign)

\[
\mathcal{L}'_p(E/K) = \frac{\text{rec}_p(q)}{\text{ord}_p(q)} \sqrt{L(E/K, 1)} \Omega_f^{-1} \cdot d^{1/2} u^2 n_f
\]

holds in \( I/I^2 \otimes \mathbb{Q} \).

For the convenience of the reader, we now briefly sketch the strategy of the proof of Theorem 1.1.

Write the conductor \( N \) of \( E \) as \( pN^+N^- \), where \( N^+ \) (respectively, \( N^- \)) is divisible only by primes that are split (respectively, inert) in \( K \). Under our assumptions, \( N^- \) has an odd number of prime factors, and \( pN^- \) is squarefree. Denote by \( B \) the definite quaternion algebra over \( \mathbb{Q} \) of discriminant \( N^- \), and fix an Eichler order \( R \) of \( B \) of level \( N^+p \). Let \( \mathcal{N} \) be the subgroup of elements of \( \mathbb{Q}_p^\times \backslash R[1/p]^\times \) whose norm has even \( p \)-adic valuation, and set \( \mathcal{N} = \text{Hom}(\Gamma, \mathbb{Z}) \). The module \( \mathcal{N} \) is a free abelian group and is equipped with the action of a Hecke algebra \( \mathbb{T} \) attached to modular forms of level \( N \) that are new at \( N^-p \). In Section 2, we also define a canonical free quotient \( \mathcal{N}_{sp} \) of \( \mathcal{N} \), which is stable for the action of \( \mathbb{T} \) and is such that the image of \( \mathbb{T} \) in \( \text{End}(\mathcal{N}_{sp}) \) corresponds to modular forms that are split multiplicative at \( p \). Let \( \pi_f \) be the idempotent of \( \mathbb{T} \otimes \mathbb{Q} \) associated with \( f \), and let \( n_f \) be a positive integer such that \( \eta_f := n_f \pi_f \) belongs to \( \mathbb{T} \). Denote by \( \mathcal{N}^f \) the submodule of \( \mathcal{N} \) on which \( \mathbb{T} \) acts via the character

\[ \phi_f : \mathbb{T} \to \mathbb{Z}, \quad T_n \mapsto a_n \]

defined by \( f \). By the multiplicity-one theorem, the module \( \mathcal{N}^f \) is isomorphic to \( \mathbb{Z} \). The operator \( \eta_f \) yields a map (denoted in the same way by an abuse of notation) \( \eta_f : \mathcal{N} \to \mathcal{N}^f \), which factors through \( \mathcal{N}_{sp} \). We define an element \( \mathcal{L}_p(\mathcal{N}_{sp}/K) \in \mathcal{N}_{sp} \otimes \mathbb{Z}[G_\infty] \), such that (up to sign)

\[ (\eta_f \otimes \text{id})(\mathcal{L}_p(\mathcal{N}_{sp}/K)) = c_p \cdot \mathcal{L}_p(E/K), \]

where \( c_p := \text{ord}_p(q) \). We recall that the derivative \( \mathcal{L}'_p(E/K) \) of \( \mathcal{L}_p(E/K) \) belongs to \( \mathcal{N}^f \otimes G_\infty = G_\infty \).
On the other hand, the module $\mathcal{N}$ is related to the theory of $p$-adic uniformization of Shimura curves. Let $\mathcal{B}$ be the indefinite quaternion algebra of discriminant $pN^-$, and let $\mathcal{R}$ be an Eichler order of $\mathcal{B}$ of level $N^+$. Write $X$ for the Shimura curve over $\mathbb{Q}$ associated with $\mathcal{R}$ (see Section 4), and write $J$ for the Jacobian of $X$. A theorem of Cherednik (see [C]), combined with the theory of Jacobians of Mumford curves (see [GvdP]), yields a rigid-analytic uniformization

$$0 \to \Lambda \to \mathcal{N} \otimes \mathbb{C}_p^\times \xrightarrow{\Phi} J(\mathbb{C}_p) \to 0,$$

where $\Lambda$ is the lattice of $p$-adic periods of $J$. The Tate uniformization (1) is obtained from the sequence (2) by applying the operator $\eta_f$ to the Hecke modules $\mathcal{N} \otimes \mathbb{C}_p^\times$ and $J(\mathbb{C}_p)$ of (2). In particular, the $p$-adic period $q$ of $E$ can be viewed as an element of the module $\mathcal{N}^f \otimes \mathbb{C}_p^\times$, and in fact one checks that it belongs to $\mathcal{N}^f \otimes \mathbb{Q}_p^\times = \mathbb{Q}_p^\times$. An explicit calculation of $p$-adic periods, combined with a formula for $L(E/K, 1)$ given in [Gr] and [Dag], proves Theorem 1.1.

A similar strategy was used in [BD2], when $p$ is inert in $K$ and the sign of the functional equation of $L(E/K, s)$ is $-1$, to obtain a $p$-adic analytic construction of a Heegner point in terms of the first derivative of an anticyclotomic $p$-adic $L$-function.

It is worth observing that an analogous strategy has not (yet) been proven to work in the case of the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$. The difficulty is that of relating in a natural way the construction of the cyclotomic $p$-adic $L$-function, which is defined in terms of modular symbols, to the $p$-adic uniformization of Shimura curves. Schneider [Sch] has proposed the definition of a $p$-adic $L$-function based on the notion, which stems directly from the theory of $p$-adic uniformization, of rigid-analytic modular symbol. Klingenberg [Kl] has proven an exceptional zero formula similar to Theorem 1.1 for this rigid-analytic $p$-adic $L$-function. However, the relation (if any) between Schneider’s $p$-adic $L$-function and the cyclotomic $p$-adic $L$-function considered in [MTT] is at present mysterious.

The reader is also referred to Teitelbaum’s paper [T], where the theory of $p$-adic uniformization of Shimura curves is used to formulate analogues of the conjectures of [MTT] for cyclotomic $p$-adic $L$-functions attached to modular forms of higher weight.

The proof by Greenberg and Stevens [GS] of the cyclotomic “exceptional zero” formula of [MTT] follows a completely different strategy from the one of this paper, and is based on Hida’s theory of $p$-adic families of modular forms.

Finally, let us mention that Kato, Kurihara, and Tsuji [KKT] recently announced more general results on the conjectures of [MTT], which make use of an Euler system constructed by Kato from modular units in towers of modular function fields.

2. Definite quaternion algebras and graphs. We keep the notation and assumptions of the introduction. In particular, we recall that $K$ is an imaginary quadratic field and $B$ is a definite quaternion algebra of discriminant $N^-$. Given a rational prime $\ell$, 

and orders $O$ of $K$ and $S$ of $B$, set

$$K_\ell := K \otimes \mathbb{Z}_\ell, \quad B_\ell := B \otimes \mathbb{Z}_\ell, \quad O_\ell := O \otimes \mathbb{Z}_\ell, \quad S_\ell := S \otimes \mathbb{Z}_\ell.$$ 

Denote by $\hat{\mathbb{Z}} = \prod \mathbb{Z}_\ell$ the profinite completion of $\mathbb{Z}$. Set

$$\hat{K} := K \otimes \hat{\mathbb{Z}}, \quad \hat{B} := B \otimes \hat{\mathbb{Z}}, \quad \hat{O} := O \otimes \hat{\mathbb{Z}} = \prod O_\ell, \quad \hat{S} := S \otimes \hat{\mathbb{Z}} = \prod S_\ell.$$ 

Fix an Eichler order $R$ of $B$ of level $N^+ + p$. Equip $R$ with an orientation, that is, a collection of algebra homomorphisms

$$o^+_{\ell} : R \to \mathbb{Z}/\ell^n \mathbb{Z}, \quad \ell^n | N^+, \quad o^-_{\ell} : R \to \mathbb{F}_{\ell^2}, \quad \ell | N^-.$$ 

The group $\hat{B}^\times$ acts transitively (on the right) on the set of Eichler orders of level $N^+ + p$ by the rule

$$S \ast \hat{b} := (\hat{b}^{-1} \hat{S} \hat{b}) \cap B.$$ 

The orientation on $R$ induces an orientation on $R \ast \hat{b}$, and the stabilizer of the oriented order $R$ is equal to $\mathbb{Q}^\times \hat{R}^\times$. This sets up a bijection between the set of oriented Eichler orders of level $N^+ + p$ and the coset space $\mathbb{Q}^\times \hat{R}^\times \backslash \hat{B}^\times$. Likewise, there is a bijection between the set of oriented Eichler orders of level $N^+ + p$ modulo conjugation by $B^\times$ and the double coset space

$$\hat{R}^\times \backslash \hat{B}^\times / B^\times.$$ 

Set $\Gamma_+ := \mathbb{Q}^\times_p \backslash R[1/p]^\times$ and, as in the introduction, let $\Gamma$ be the image in $\Gamma_+$ of the elements in $R[1/p]^\times$ whose reduced norm has even $p$-adic valuation.

**Lemma 2.1.** $\Gamma$ has index 2 in $\Gamma_+$.

**Proof.** See [BD2, Lemma 1.5].

Let $\mathcal{T}$ be the Bruhat-Tits tree associated with the local algebra $B_p$. The set of vertices $\mathcal{V}(\mathcal{T})$ of $\mathcal{T}$ is equal to the set of maximal orders in $B_p$. The set $\mathcal{E}(\mathcal{T})$ of oriented edges of $\mathcal{T}$ is equal to the set of oriented Eichler orders of level $p$ in $B_p$. Thus, $\mathcal{E}(\mathcal{T})$ can be identified with the coset space $\mathbb{Q}^\times_p R_p^\times \backslash B_p^\times$, by mapping $b_p \in B_p^\times$ to $R_p \ast b_p = b_p^{-1} R_p b_p$. Similarly, if $R_p$ is a maximal order in $B_p$ containing $R_p$, we identify $\mathcal{V}(\mathcal{T})$ with the coset space $\mathbb{Q}^\times_p R_p^\times \backslash B_p^\times$. Define the graphs

$$\mathcal{G} := \mathcal{T} / \Gamma, \quad \mathcal{G}_+ := \mathcal{T} / \Gamma_+.$$ 

By strong approximation (see [Vi, p. 61]), there is an identification

$$\mathcal{E}(\mathcal{G}_+) = \hat{R}^\times \backslash \hat{B}^\times / B^\times,$$
of the set of oriented edges of $\mathcal{G}_+$ with the set of conjugacy classes of oriented Eichler orders of level $N^+p$.

Fixing a vertex $v_0$ of $\mathcal{T}$ gives rise to an orientation of $\mathcal{T}$ in the following way. A vertex of $\mathcal{T}$ is called even (respectively, odd) if it has even (respectively, odd) distance from $v_0$. The direction of an edge is said to be positive if it goes from the even to the odd vertex. Since $\Gamma$ sends even vertices to even ones, and odd vertices to odd ones, the orientation of $\mathcal{T}$ induces an orientation of $\mathcal{G}$. Define a map

$$\kappa : \mathcal{E}(\mathcal{G}) \to \mathcal{E}(\mathcal{G}_+)$$

from the set of edges of $\mathcal{G}$ to the set of oriented edges of $\mathcal{G}_+$, by mapping an edge \((v, v')\) (mod $\Gamma$) of $\mathcal{G}$, where $v$ and $v'$ are vertices of $\mathcal{T}$ and we assume that $v$ is even, to the oriented edge $((v, v'))$ (mod $\Gamma_+$) of $\mathcal{G}_+$.

**Lemma 2.2.** The map $\kappa$ is a bijection.

*Proof.* Suppose that $((v, v'))$ (mod $\Gamma_+$) $= (u, u')$ (mod $\Gamma_+$). Thus, there is $\gamma \in \Gamma_+$ such that $\gamma v = u$ and $\gamma v' = u'$. If $v$ and $u$ are both even, $\gamma$ must belong to $\Gamma$, and this proves the injectivity of $\kappa$. As for surjectivity, for all $((v, v'))$ (mod $\Gamma_+$) the image by $\kappa$ of $\{(v, v')\}$ (mod $\Gamma$) is the image by $\kappa$ of $\{(v, v')\}$ (mod $\Gamma$) if $v$ is even, and of $\{wv, vw'\}$ (mod $\Gamma$), where $w$ is any element of $\Gamma_+ - \Gamma$, if $v$ is odd.

Given two vertices $v$ and $v'$ of $\mathcal{T}$, write path($v, v'$) for the natural image in $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ of the unique geodesic on $\mathcal{T}$ joining $v$ with $v'$. For example, if $v$ and $v'$ are even vertices joined by four consecutive edges $e_1, e_2, e_3, e_4$, by our convention for orienting the edges of $\mathcal{T}$, path($v, v'$) is the image in $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ of $e_1 - e_2 + e_3 - e_4$.

There is a coboundary map

$$\partial^* : \mathbb{Z}[\mathcal{V}(\mathcal{G})] \to \mathbb{Z}[\mathcal{E}(\mathcal{G})],$$

which maps the image in $\mathcal{V}(\mathcal{G})$ of an odd (respectively, even) vertex $v$ of $\mathcal{T}$ to the image in $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ of the formal sum of the edges of $\mathcal{T}$ emanating from $v$ (respectively, the opposite of this sum). There is also a boundary map

$$\partial_* : \mathbb{Z}[\mathcal{E}(\mathcal{G})] \to \mathbb{Z}[\mathcal{V}(\mathcal{G})],$$

which maps an edge $e$ to the difference $v' - v$ of its vertices, where $v$ is the even vertex and $v'$ is the odd vertex of $e$. The integral homology (respectively, the integral cohomology) of the graph $\mathcal{G}$ is defined by $H_1(\mathcal{G}, \mathbb{Z}) = \ker(\partial_*)$ (respectively, $H^1(\mathcal{G}, \mathbb{Z}) = \coker(\partial^*)$).

Let

$$\langle , \rangle : \mathbb{Z}[\mathcal{E}(\mathcal{G})] \times \mathbb{Z}[\mathcal{E}(\mathcal{G})] \to \mathbb{Z}$$

be the pairing on $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ defined by the rule $\langle e_i, e_j \rangle := \omega_{ij} \delta_{ij}$, where the $e_i$ are the elements of the standard basis of $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ and $\omega_{ij}$ is the order of the stabilizer in $\Gamma$ of a lift of $e_i$ to $\mathcal{T}$. Likewise, let

$$\langle\langle , \rangle\rangle : \mathbb{Z}[\mathcal{V}(\mathcal{G})] \times \mathbb{Z}[\mathcal{V}(\mathcal{G})] \to \mathbb{Z}$$
be the pairing on $\mathbb{Z}[[V(\mathfrak{g})]]$ defined by $\langle v_i, v_j \rangle := \omega_{ij} \delta_{ij}$, where the $v_i$ are the elements of the standard basis of $\mathbb{Z}[[V(\mathfrak{g})]]$ and $\omega_{ij}$ is the order of the stabilizer in $\Gamma$ of a lift of $v_i$ to $\overline{\Gamma}$.

We use the notation $\mathcal{M}$ to indicate the module $H^1(\mathfrak{g}, \mathbb{Z})$. Let $\overline{\Gamma}$ be the maximal torsion-free abelian quotient of $\Gamma$. As in the introduction, write $\mathcal{N}$ for $\text{Hom}(\overline{\Gamma}, \mathbb{Z})$. Given an element $\gamma \in \Gamma$, denote by $\overline{\gamma}$ the natural image of $\gamma$ in $\overline{\Gamma}$.

**Lemma 2.3.** (i) The map from $\overline{\Gamma}$ to $H_1(\mathfrak{g}, \mathbb{Z})$ that sends $\overline{\gamma} \in \overline{\Gamma}$ to the cycle path$(v_0, \gamma v_0)$, where $v_0$ is any vertex of $\mathfrak{g}$ and $\gamma$ is any lift of $\overline{\gamma}$ to $\Gamma$, is an isomorphism.

(ii) The map from $\mathcal{M}$ to $\mathcal{N}$ that sends $m \in \mathcal{M}$ to the homomorphism

$$\overline{\gamma} \mapsto \langle \text{path}(v_0, \gamma v_0), m \rangle$$

is injective and has finite cokernel.

**Proof (Sketch).** Part (i) is proved in [Se]. Part (ii) follows from part (i) and from the fact that the maps $\partial^+$ and $\partial_+$ are adjoint with respect to the pairings defined above.

Write $\mathcal{M}_{sp}$ for the maximal torsion-free quotient of $\mathcal{M}/(w+1)\mathcal{M}$, with $w \in \Gamma_+ - \Gamma$. By part (i) of Lemma 2.3, the action of $w \in \Gamma_+ - \Gamma$ on $H_1(\mathfrak{g}, \mathbb{Z})$ induces an action of $w$ on $\mathcal{N}$. Write $\mathcal{N}_{sp}$ for the maximal torsion-free quotient of $\mathcal{N}/(w+1)\mathcal{N}$. We have an induced map from $\mathcal{M}_{sp}$ to $\mathcal{N}_{sp}$ that is injective and has finite cokernel.

The module $\mathbb{Z}[\mathfrak{e}(\mathfrak{g})]$ is equipped with the natural action of an algebra $\overline{\mathbb{T}}$ generated over $\mathbb{Z}$ by the Hecke correspondences $T_{\ell}$ for $\ell \mid N$ and $U_{\ell}$ for $\ell \nmid N$, coming from its double coset description: see [BD1, Sec. 1.5]. The module $H_1(\mathfrak{g}, \mathbb{Z})$ is stable under the action of $\overline{\mathbb{T}}$. Hence, by part (i) of Lemma 2.3, the algebra $\overline{\mathbb{T}}$ also acts on the modules $\mathcal{N}$ and $\mathcal{N}_{sp}$. Let $\mathbb{T}$ and $\mathbb{T}_{sp}$ denote the image of $\overline{\mathbb{T}}$ in $\text{End}(\mathcal{N})$ and $\text{End}(\mathcal{N}_{sp})$, respectively. Thus, there are natural surjections $\overline{\mathbb{T}} \twoheadrightarrow \mathbb{T} \twoheadrightarrow \mathbb{T}_{sp}$. By an abuse of notation, we denote by $T_{\ell}$ and $U_{\ell}$ also the natural images in $\mathbb{T}$ and $\mathbb{T}_{sp}$ of $T_{\ell}$ and $U_{\ell}$.

The next proposition clarifies the relation between the modules $\mathcal{N}$ and $\mathcal{N}_{sp}$ and the theory of modular forms.

**Proposition 2.4.** Let $\phi$ be an algebra homomorphism from $\mathbb{T}$ (respectively, $\mathbb{T}_{sp}$) to $\mathbb{C}$, and let $a_n := \phi(T_n)$. Then, the $a_n$ are the Fourier coefficients of a normalized eigenform of level $N$, which is new at $N^- p$ (respectively, is new at $N^- p$ and is split multiplicative at $p$). Conversely, any such modular form arises as above from a character of $\mathbb{T}$ (respectively, $\mathbb{T}_{sp}$).

**Proof.** Eichler’s trace formula identifies the Hecke-module $\mathbb{Z}[\mathfrak{e}(\mathfrak{g})]$ with a space of modular forms of level $N$ that are new at $N^-$. Moreover, the algebra $\mathbb{T}$ can also be viewed as the Hecke algebra of the module $\mathcal{M}$ defined above, and Proposition 1.4 of [BD2] shows that $\mathcal{M}$ is equal to the “$p$-new” quotient of $\mathbb{Z}[\mathfrak{e}(\mathfrak{g})]$. This proves the statement of Proposition 2.4 concerning characters of $\mathbb{T}$. The abelian variety associated to a $p$-new modular form $f$ is split multiplicative at $p$ if and only if
Moreover, the Atkin-Lehner involution at $p$ acts on a $p$-new modular form as $-U_p$, and acts on $M$ as $\Gamma_+//\Gamma$. This concludes the proof of Proposition 2.4.

Modular parametrizations, I. We now make a specific choice of the operator $\eta_f$ (where $f$ is the newform of level $N$ attached to $E$) considered in the introduction. It is used in formulating the results in the sequel of the paper.

As stated in Lemma 2.3, $\overline{\omega}_{\text{am}, \text{am}}$ can be identified with the homology group $H_1(\mathbb{X}, \mathbb{Z}) \subset \mathbb{Z}[\mathcal{E}(\mathfrak{g})]$. Thus, when convenient, we tacitly view elements of $\overline{\omega}_{\text{am}, \text{am}}$ as contained in $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]$. The restriction of the pairing on $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]$ defined above to $\overline{\omega}_{\text{am}, \text{am}}$ yields the monodromy pairing (denoted in the same way by an abuse of notation)

$$\langle \, , \rangle : \overline{\omega}_{\text{am}, \text{am}} \times \overline{\omega}_{\text{am}, \text{am}} \rightarrow \mathbb{Z}.$$  

Let $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]^f$ (respectively, $\overline{\omega}_{\text{am}, \text{am}}^f$) be the submodule of $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]$ (respectively, $\overline{\omega}_{\text{am}, \text{am}}$) on which $\tilde{T}$ (respectively, $\Gamma$) acts via the character associated with $f$. Note that the quotient of $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]$ by $\tilde{T}$ is torsion free, and thus there is a canonical identification $\mathbb{Z}[\mathcal{E}(\mathfrak{g})]^f / \overline{\omega}_{\text{am}, \text{am}}^f \simeq \mathbb{Z}$.

Define the “modular parametrizations”

$$\pi_* : \tilde{T} \rightarrow \overline{\omega}_{\text{am}, \text{am}}^f, \quad \pi^* : \overline{\omega}_{\text{am}, \text{am}}^f \rightarrow \tilde{T},$$

by $\pi_*(e) := \langle e, f \rangle e^f$ and $\pi^*(e^f) := e^f$. Since

$$(\pi^* \circ \pi_*)^2 = \langle e^f, f \rangle (\pi^* \circ \pi_*),$$

we obtain that $\pi^* \circ \pi_*$ is equal to $\langle e^f, f \rangle \pi_f$, where $\pi_f$ is the idempotent of $\mathbb{T} \otimes \mathbb{Q}$ associated with $f$. From now on, we assume that the operator $\eta_f$ is defined by

$$\eta_f := \pi^* \circ \pi_*,$$

so that the integer $n_f$ is equal to $\langle e^f, f \rangle$.

As observed in the introduction, the operator $\eta_f$ induces a map $N \rightarrow \mathbb{Z}$, which is well defined up to sign. Since $f$ has split multiplicative reduction at $p$, this map factors through a map $N_{sp} \rightarrow \mathbb{Z}$. By an abuse of notation, we indicate both of the above maps by $\eta_f$.

Remark 2.5. The module $\tilde{T}$ can be identified with the character group associated with the reduction modulo $p$ of Pic$^0(X)$, where $X$ is the Shimura curve considered in the introduction. As is explained in Section 4, the map $\pi^* \circ \pi_*$ on $\tilde{T}$ is induced by functoriality from a modular parametrization Pic$^0(X) \rightarrow E$.

3. The $p$-adic $L$-function. Let $\mathcal{O}_n$ denote the order of $K$ of conductor $cp^n$, $n \geq 0$. (We usually write $\mathcal{O}$ instead of $\mathcal{O}_0$.) Equip the orders $\mathcal{O}_n$ with compatible orientations, that is, with compatible algebra homomorphisms

$$\overline{\omega}_+^+ : \mathcal{O}_n \rightarrow \mathbb{Z}/\ell^m \mathbb{Z}, \quad \ell^m \parallel N^+ p,$$
\[
\mathcal{O}_n \rightarrow \mathbb{F}_\ell^2, \quad \ell \mid N^-.
\]

An algebra homomorphism of \( \mathcal{O}_n \) into an oriented Eichler order \( S \) of level \( N^+p \) is called an oriented optimal embedding if it respects the orientation on \( \mathcal{O}_n \) and on \( S \), and does not extend to an embedding of a larger order into \( S \). Consider pairs \((R_\xi, \xi)\), where \( R_\xi \) is an oriented Eichler order of level \( N^+p \) and \( \xi \) is an element of \( \text{Hom}(K, B) \) that restricts to an oriented optimal embedding of \( \mathcal{O}_n \) into \( R_\xi \). A Gross point of conductor \( cp^n (n \geq 0) \) is a pair as above, taken modulo the action of \( B^\times \).

By our previous remarks, a Gross point can be viewed naturally as an element of the double coset space

\[
W := (\hat{\mathbb{K}}^\times \backslash \hat{\mathbb{K}}^\times / \text{Hom}(K, B))/B^\times.
\]

(See [Gr, Sec. 3] for more details.) Strong approximation gives the identification

\[
W = (\hat{\mathbb{K}}(\mathcal{T}) \times \text{Hom}(K, B))/\Gamma_+.
\]

By Lemma 2.2, there is a natural map of \( \mathbb{Z} \)-modules \( \mathbb{Z}[W] \rightarrow \mathbb{Z}[\hat{\mathbb{K}}(\mathcal{T})] \), where \( \mathbb{Z}[W] \) is the module of finite formal \( \mathbb{Z} \)-linear combinations of elements of \( W \). The Hecke algebra \( \mathbb{K} \) of \( \mathbb{Z}[\hat{\mathbb{K}}(\mathcal{T})] \) acts naturally also on \( \mathbb{Z}[W] \) (see [BD1, Sec. 1.5]), in such a way that the above map is \( \mathbb{K} \)-equivariant.

The group \( G_n = \text{Pic}(\mathcal{O}_n) = \hat{\mathbb{K}}^\times /\mathbb{K}^\times \) acts simply transitively on the Gross points of conductor \( cp^n \) by the rule

\[
\sigma(R_\xi, \xi) := (R_\xi \ast \hat{\xi}(\sigma)^{-1}, \xi),
\]

where \( \hat{\xi} \) denotes the extension of \( \xi \) to a map from \( \hat{\mathbb{K}} \) to \( \hat{B} \).

Now, fix a Gross point \( P_0 = (R_0, \xi_0) \) (mod \( B^\times \)) of conductor \( c \). By the above identification, \( P_0 \) corresponds to a pair \((\hat{e_0}, \xi_0) \in \hat{\mathbb{K}}(\mathcal{T}) \times \text{Hom}(K, B)\), modulo the action of \( \Gamma_+ \). As above, the origin \( v_0 \) of \( \hat{e_0} \) determines an orientation of \( \mathcal{T} \). Let \( \hat{e} \) be one of the \( p \) oriented edges of \( \mathcal{T} \) originating from \( \hat{e_0} \). All the Gross points corresponding to pairs \((\hat{e}, \xi_0)\) as above have conductor \( cp \), except for one, which has conductor \( c \). Fix an end

\[
(\hat{e_0}, \hat{e}_1, \ldots, \hat{e}_n, \ldots)
\]
such that \((\hat{e}_1, \xi_0)\) defines a Gross point of conductor \( cp \). Then, \((\hat{e}_n, \xi_0)\) defines a Gross point \( P_n \) of conductor \( cp^n \), for all \( n \geq 0 \).

Denote by \( \text{Norm}_{H_{n+1}/H_n} \) the norm operator \( \sum_{g \in \text{Gal}(H_{n+1}/H_n)} g \).

**Lemma 3.1.** (1) Let \( u = (1/2)^\#C^\times \). The equality

\[
U_p P_0 = u \text{Norm}_{H_1/H_0} P_1 + \sigma_p P_0
\]

holds in \( \mathbb{Z}[W] \) for a prime \( p \) above \( p \), where \( \sigma_p \in \text{Gal}(H_0/K) \) denotes the image of \( p \) by the Artin map.

(2) For \( n \geq 1 \),

\[
U_p P_n = \text{Norm}_{H_{n+1}/H_n} P_{n+1}.
\]
Proof. The proof follows from the definition of the operator $U_p$ (see [BD1, Sec. 1.5]) and the action of $\text{Pic}(\mathcal{O}_n)$ on the Gross points.

Figure 1, drawn in the case where $p = 2$, illustrates geometrically the relation between the Galois action and the action of the Hecke correspondence $U_p$.

By Lemma 2.3, the natural map from $\mathbb{Z}[W]$ to $\mathbb{Z}[\mathcal{E}(\mathcal{G})]$ induces maps from $\mathbb{Z}[W]$ to the modules $\mathcal{N}$ and $\mathcal{N}_{sp}$. These maps are Hecke-equivariant.

The Gross points $P_n$ give rise to a $p$-adic distribution on $G_{\infty}$ with values in the module $\mathcal{N}_{sp}$ as follows. Given $g \in G_n$, denote by $\mathcal{E}_n^g$ the natural image of $P_n^g$ in $\mathcal{N}_{sp}$. For $n \geq 0$, define the truncated $p$-adic $L$-function

$$\mathcal{L}_{p,n}(\mathcal{N}_{sp}/K) := \sum_{g \in G_n} \mathcal{E}_n^g \cdot g^{-1} \in \mathcal{N}_{sp} \otimes \mathbb{Z}[G_n].$$

Note that $\mathcal{L}_{p,n}(\mathcal{N}_{sp}/K)$ is well defined up to multiplication by elements of $G_n$.

For $n \geq 1$, let $\nu_n : \mathbb{Z}[G_n] \to \mathbb{Z}[G_{n-1}]$ be the natural projection of group rings.

Lemma 3.2. (1) The equality

$$\nu_1(\mathcal{L}_{p,1}(\mathcal{N}_{sp}/K)) = u^{-1}(1 - \sigma_p)\mathcal{L}_{p,0}(\mathcal{N}_{sp}/K)$$

holds in $\mathcal{N}_{sp} \otimes \mathbb{Z}[G_0]$.

(2) For $n \geq 2$, the equality

$$\nu_n(\mathcal{L}_{p,n}(\mathcal{N}_{sp}/K)) = \mathcal{L}_{p,n-1}(\mathcal{N}_{sp}/K)$$

holds in $\mathcal{N}_{sp} \otimes \mathbb{Z}[G_{n-1}]$. 

---

Figure 1
Proof. By Proposition 2.4, the operator \( U_p \) acts as \(+1\) on \( \mathcal{N}_{sp} \). The claim follows from Lemma 3.1 and the fact that \( \mathcal{N}_{sp} \) is torsion free.

Define the \( p \)-adic \( L \)-function attached to \( \mathcal{N}_{sp} \) to be

\[
\mathcal{L}_p (\mathcal{N}_{sp}/K) := \lim_{\rightarrow n} \mathcal{L}_{p,n}(\mathcal{N}_{sp}/K) \in \mathcal{N}_{sp} \otimes \mathbb{Z}[[G_\infty]].
\]

We now define the \( p \)-adic \( L \)-function attached to \( E \). Observe that the maximal quotient \( \bar{\omega}_{\text{am}}^m \) of \( \bar{\omega}_{\text{am}}^m \) on which \( T \) acts via the character associated with \( f \) is isomorphic to \( \mathbb{Z} \). Let \( e_f \) be a generator of \( \bar{\omega}_{\text{am}}^m \). The monodromy pairing on \( \bar{\omega}_{\text{am}}^m \) induces a \( \mathbb{Z} \)-valued pairing on \( \bar{\omega}_{\text{am}}^m \). Write \( \hat{c}_p \) for the positive integer \( |\langle e_f, e_f \rangle| \).

Lemma 3.3. The element \((\eta_f \otimes \text{id})(\mathcal{L}_p(\mathcal{N}_{sp}/K)) \in \mathbb{Z}[[G_\infty]]\) is divisible by \( \hat{c}_p \).

Proof. Consider the maps

\[
\tilde{\pi}_*: \mathbb{Z}[\mathcal{E}(\mathcal{N})] \rightarrow \mathbb{Z}[\mathcal{E}(\mathcal{N})]^f, \quad \tilde{\pi}^*: \mathbb{Z}[\mathcal{E}(\mathcal{N})]^f \rightarrow \mathbb{Z}[\mathcal{E}(\mathcal{N})]
\]

defined by \( \tilde{\pi}_*(e) := \langle e, e_f \rangle e_f \) and \( \tilde{\pi}^*(e_f) := e_f \). (The modular parametrizations \( \pi_* \) and \( \pi^* \) introduced in Section 2 are obtained from these maps by restriction.) Hence, \( \tilde{\eta}_f := \tilde{\pi}^* \circ \tilde{\pi}_* \) is an element of \( \tilde{T} \), equal to \( \langle e_f, e_f \rangle \tilde{\pi}_f \), where \( \tilde{\pi}_f \) is the idempotent in \( \tilde{T} \otimes \mathbb{Q} \) associated with \( f \). We have a commutative diagram

\[
\begin{array}{ccc}
\mathbb{Z}[\mathcal{E}(\mathcal{N})] & \rightarrow & \mathcal{N} \\
\tilde{\eta}_f & \downarrow & \eta_f \\
\mathbb{Z}[\mathcal{E}(\mathcal{N})]^f & \longrightarrow & \mathcal{N}^f,
\end{array}
\]

where the upper horizontal map is defined in Lemma 2.3, and the lower horizontal map is the restriction of the upper one. Note that \( \mathcal{N}^f \) is equal to \( \text{Hom}(\tilde{T}_f, \mathbb{Z}) \) and therefore is generated by the homomorphism \( e_f \mapsto 1 \). With our choices of generators for \( \mathbb{Z}[\mathcal{E}(\mathcal{N})]^f \) and \( \mathcal{N}^f \), the lower map of the above diagram is described as multiplication by the integer \( \langle e_f, e_f \rangle \). The proof of Lemma 3.2 also shows that mapping the Gross points of conductor \( cp^n \) to \( \mathbb{Z}[\mathcal{E}(\mathcal{N})]^f \) by the map \( \tilde{\eta}_f \) yields a \( p \)-adic distribution in \( \mathbb{Z}[\mathcal{E}(\mathcal{N})]^f \otimes \mathbb{Z}[[G_\infty]] \). By the above diagram, the image of this distribution in \( \mathcal{N}^f \otimes \mathbb{Z}[[G_\infty]] \) is equal to \((\eta_f \otimes \text{id})(\mathcal{L}_p(\mathcal{N}_{sp}/K)) \). This proves the lemma.

Remark 3.4. In Section 4, we show that the integers \( \hat{c}_p \) and \( c_p \) are equal.

Define the \( p \)-adic \( L \)-function attached to \( E \) to be

\[
\mathcal{L}_p(E/K) = \hat{c}_p^{-1}(\eta_f \otimes \text{id})(\mathcal{L}_p(\mathcal{N}_{sp}/K)) \in \mathbb{Z}[[G_\infty]].
\]

Observe that \( \mathcal{L}_p(\mathcal{N}_{sp}/K) \) and \( \mathcal{L}_p(E/K) \) are well defined up to multiplication by elements of \( G_\infty \).

Recall the quantities \( \Omega_f \) and \( d \) defined in the introduction.
Theorem 3.5. Let $\chi : G_\infty \to \mathbb{C}^\times$ be a finite-order character of conductor $cp^n$, with $n \geq 1$. Then the equality
$$
\left| \chi(\mathcal{L}_p(E/K)) \right|^2 = \frac{L(E/K, \chi, 1)}{\Omega_f} \sqrt{d} \cdot (n_f u)^2
$$
holds.

Proof. See [Gr], [Dag], and [BD1, Sec. 2.10].

Remark 3.6. (1) Theorem 3.5 suggests that $\mathcal{L}_p(E/K)$ should really be viewed as the square root of a $p$-adic $L$-function, and hence we should define the anticyclotomic $p$-adic $L$-function of $E$ to be $\mathcal{L}_p(E/K) \otimes \mathcal{L}_p(E/K)^*$, where $*$ denotes the involution of $\mathbb{Z}[[G_\infty]]$ given on grouplike elements by $g \mapsto g^{-1}$. See Section 2.7 of [BD1] for more details.

(2) More generally, the $p$-adic $L$-function $\mathcal{L}_p(\mathcal{N}_{sp}/K)$ interpolates special values of the complex $L$-series attached to the modular forms on $\mathbb{T}_{sp}$ (described in Proposition 2.4).

Let $\sigma_p$ be as in Lemma 3.1. Denote by $H$ the subextension of $H_0$ that is fixed by $\sigma_p$, and set
$$
G_n := \text{Gal}(H_n/H), \quad G_\infty := \text{Gal}(H_\infty/H),
$$
$$
\Sigma := \text{Gal}(H_0/H) = G_0, \quad \Delta := \text{Gal}(H/K).
$$
Note the exact sequences of Galois groups
$$
0 \to G_n \to G_\infty \to \Delta \to 0,
$$
$$
0 \to G_\infty \to G_\infty \to \Delta \to 0.
$$
The group $\Delta$ is naturally identified with the Picard group $\text{Pic}(\mathcal{O}[1/p])$, and $G_\infty$ is equal to the image of the reciprocity map $\text{rec}_p : \mathbb{Q}_p^\times \to G_\infty$ (where we identified $\mathbb{Q}_p^\times$ with $K_p^\times$). Let $I$ be the kernel of the augmentation map $\mathbb{Z}[[G_\infty]] \to \mathbb{Z}$, and let $I_\Delta$ be the kernel of the augmentation map $\mathbb{Z}[[G_\infty]] \to \mathbb{Z}[\Delta]$.

Lemma 3.7. (i) $\mathcal{L}_p(\mathcal{N}_{sp}/K)$ belongs to $\mathcal{N}_{sp} \otimes I_\Delta$.
(ii) $\mathcal{L}_p(E/K)$ belongs to $I_\Delta$.

Proof. There are canonical isomorphisms
$$
\mathbb{Z}[[G_\infty]]/I_\Delta = \mathbb{Z}[G_n]/I_{\Delta,n} = \mathbb{Z}[\Delta],
$$
where $I_{\Delta,n}$ is the natural image of $I_\Delta$ in $\mathbb{Z}[G_n]$. By Lemma 3.2, the image of $\mathcal{L}_p(\mathcal{N}_{sp}/K)$ in $\mathcal{N}_{sp} \otimes (\mathbb{Z}[[G_\infty]]/I_\Delta)$ is equal to the image of $\mathcal{L}_{p,1}(\mathcal{N}_{sp}/K)$ in $\mathcal{N}_{sp} \otimes (\mathbb{Z}[G_1]/I_{\Delta,1}) = \mathcal{N}_{sp} \otimes \mathbb{Z}[\Delta]$. The first part of the lemma now follows from Lemma 3.2(1). The second part follows directly from the first.
Since $I_\Delta$ is contained in $I$, the element $\mathcal{L}_p(N_{sp}/K)$ belongs to $N_{sp} \otimes I$ and $\mathcal{L}_p(E/K)$ belongs to $I$. Denote by
\[
\mathcal{L}'_p(N_{sp}/K), \quad \mathcal{L}'_p(N_{sp}/H)
\]
the natural image of $\mathcal{L}_p(N_{sp}/K)$ in $N_{sp} \otimes I/I^2 = N_{sp} \otimes G_\infty$ and $N_{sp} \otimes I_\Delta/I^2_\Delta = N_{sp} \otimes \mathbb{Z}[\Delta] \otimes G_\infty$, respectively. Likewise, let
\[
\mathcal{L}'_p(E/K), \quad \mathcal{L}'_p(E/H)
\]
be the natural image of $\mathcal{L}_p(E/K)$ in $I/I^2 = G_\infty$ and $I_\Delta/I^2_\Delta = \mathbb{Z}[\Delta] \otimes G_\infty$, respectively. The above elements should be viewed as derivatives of $p$-adic $L$-functions at the central point.

In order to carry out the calculations of the next sections, it is useful to observe that the derivatives $\mathcal{L}'_p(N_{sp}/K)$ and $\mathcal{L}'_p(N_{sp}/H)$ can be expressed in terms of the derivatives of certain partial $p$-adic $L$-functions. Set $h := \#(\Delta)$. Fix Gross points of conductor $c$,
\[
P_0 = P_0^1, \ldots, P_0^h,
\]
corresponding to pairs $(R_i^0, \xi_0^i)$, $i = 1, \ldots, h$, which are representatives for the $\Sigma$-orbits of the Gross points of conductor $c$. Writing $[P_0^i]$ for the $\Sigma$-orbit of $P_0^i$, let $\delta_i$ be the element of $\omega_{\text{Sigmam}}$ such that
\[
[\delta_i P_0^1] = [P_0^i].
\]
Suppose that $P_0^i$ corresponds to a pair $(\tilde{\epsilon}_0(i), \xi_0^i) \in \tilde{\epsilon}(\mathcal{F}) \times \text{Hom}(K, B)$, modulo the action of $\Gamma_+$. Fix ends $(\tilde{\epsilon}_0(i), \tilde{\epsilon}_1(i), \ldots, \tilde{\epsilon}_n(i), \ldots)$ such that $(\tilde{\epsilon}_1(i), \xi_0^i)$ defines a Gross point of conductor $cp$. Thus, $(\tilde{\epsilon}_n(i), \xi_0^i)$ defines a Gross point $P_n^i$ of conductor $cp^h$, for all $n \geq 0$. For $g \in G_n$, let $e_n(i)^g$ denote the natural image of $(P_n^i)^g$ in $N_{sp}$. Let
\[
\mathcal{L}_{p,n}(N_{sp}/H, P_0^i) := \sum_{g \in G_n} e_n(i)^g \cdot g^{-1} \in N_{sp} \otimes \mathbb{Z}[G_n].
\]
The proof of Lemma 3.2 also shows that the elements $\mathcal{L}_{p,n}(N_{sp}/H, P_0^i)$ are compatible under the maps induced by the natural projections of group rings. Thus, we may define the partial $p$-adic $L$-function attached to $N_{sp}$ and $P_0^i$ to be
\[
\mathcal{L}_p(N_{sp}/H, P_0^i) := \lim_{\longrightarrow} \mathcal{L}_{p,n}(N_{sp}/H, P_0^i) \in N_{sp} \otimes \mathbb{Z}[[G_\infty]].
\]
We observe that $\mathcal{L}_p(N_{sp}/H, P_0^i)$ depends only on the $\Sigma$-orbit of $P_0^i$, up to multiplication by elements of $G_\infty$. 
Let $I_H$ be the kernel of the augmentation map $\mathbb{Z}[G_\infty] \to \mathbb{Z}$. Like in the proof of Lemma 3.7, one checks that $L_p(N_{sp}/H, P^i_0)$ belongs to $I_H$. Write $L_p'(N_{sp}/H, P^i_0)$ for the natural image of $L_p(N_{sp}/H, P^i_0)$ in $N_{sp} \otimes I_H/I_H^2 = N_{sp} \otimes G_\infty$. Thus,

$$L_p'(N_{sp}/H, P^i_0) = \lim_{\longrightarrow n} L_{p,n}'(N_{sp}/H, P^i_0),$$

where

$$L_{p,n}'(N_{sp}/H, P^i_0) = \sum_{g \in G_n} e_n(i)^g \otimes g^{-1}. \quad (3)$$

We obtain the following lemma directly.

**Lemma 3.8.** (i)

$$L_p'(N_{sp}/K) = \sum_{i=1}^h L_p'(N_{sp}/H, P^i_0).$$

(ii)

$$L_p'(N_{sp}/H) = \sum_{i=1}^h L_p'(N_{sp}/H, P^i_0) \cdot \delta_i^{-1}.$$

### 4. The theory of $p$-adic uniformization of Shimura curves.

For more details on the results stated in this section, the reader is referred to [BC], [C], [Dr], [GvdP], and [BD2].

Let $B$ be the indefinite quaternion algebra over $\mathbb{Q}$ of discriminant $N_0 = \pm p$, and let $\mathcal{O}$ be an Eichler order of $B$ of level $N_0$. Denote by $X$ the Shimura curve over $\mathbb{Q}$ associated with the order $\mathcal{O}$. We refer the reader to [BC] and [BD2, Sec. 4] for the definition of $X$ via moduli. Here we content ourselves with recalling Cherednik’s theorem, which describes a rigid-analytic uniformization of $X$. Write $\mathcal{H}_p := \mathbb{C}_p - \mathbb{Q}_p$ for the $p$-adic upper half plane. The group $GL_2(\mathbb{Q}_p)$ acts (on the left) on $\mathcal{H}_p$ by linear fractional transformations. Thus, fixing an isomorphism

$$\psi : B_p \to M_2(\mathbb{Q}_p)$$

induces an action of $\Gamma$ on $\mathcal{H}_p$. This action is discontinuous, and the rigid-analytic quotient $\Gamma \backslash \mathcal{H}_p$ defines the $\mathbb{C}_p$-points of a nonsingular curve $\mathcal{X}$ over $\mathbb{Q}_p$. The curves $X$ and $\mathcal{X}$ are equipped with the action of Hecke algebras $\mathbb{T}_X$ and $\mathbb{T}_\mathcal{X}$, respectively (see [BC], [BD1]).

By Lemma 2.1, the action of $\Gamma_+ \backslash \Gamma$ induces an involution $W$ of $\mathcal{X}$. Let $\mathbb{Q}_{p^2}$ be the unique unramified quadratic extension of $\mathbb{Q}_p$ contained in $\mathbb{C}_p$, and let $\tau$ be the generator of $Gal(\mathbb{Q}_{p^2}/\mathbb{Q}_p)$. Denote by $\xi \in H^1(\tau, Aut(\mathcal{X}))$ the class of the cocycle mapping $\tau$ to $W$, and write $\mathcal{X}_\xi$ for the curve over $\mathbb{Q}_p$ obtained by twisting $\mathcal{X}$ by $\xi$. 
Theorem 4.1 (Cherednik). There is a Hecke-equivariant isomorphism \(X \cong \mathcal{X}\) of curves over \(\mathbb{Q}_p\). In particular, \(X\) and \(\mathcal{X}\) are isomorphic over \(\mathbb{Q}_p^2\).

Proof. See [C], [Dr], [BC].

Building on Theorem 4.1, the results in [GvdP] yield a rigid-analytic description of the jacobian of \(X\). If \(D = P_1 + \cdots + P_r - Q_1 - \cdots - Q_r \in \text{Div}^0(\mathcal{H}_p)\) is a divisor of degree zero on \(\mathcal{H}_p\), define the theta function
\[
\vartheta(z; D) = \prod_{\epsilon \in \Gamma} \frac{(z - \epsilon P_1) \cdots (z - \epsilon P_r)}{(z - \epsilon Q_1) \cdots (z - \epsilon Q_r)}.
\]
Write \(\bar{\delta}\) for the natural image in \(\bar{\Gamma}\) of an element \(\delta\) of \(\Gamma\). For all \(\delta\) in \(\Gamma\), the above theta function satisfies the functional equation
\[
\vartheta(\delta z; D) = \phi_D(\bar{\delta}) \vartheta(z; D),
\]
where \(\phi_D\) is an element of \(\text{Hom}(\bar{\Gamma}, \mathbb{C}_p) = \mathcal{N} \otimes \mathbb{C}_p^\times\) that does not depend on \(z\). For \(\gamma \in \Gamma\), the number \(\phi_D(\gamma z; - (\bar{\delta}))\) does not depend on the choice of \(z \in \mathcal{H}_p\) and depends only on the image of \(\gamma\) in \(\bar{\Gamma}\). This gives rise to a pairing
\[
[\ , ] : \bar{\Gamma} \times \bar{\Gamma} \to \mathbb{Q}_p^\times.
\]
The pairing \([\ , ]\) is bilinear and symmetric. The next proposition explains the relation between \([\ , ]\) and the monodromy pairing \(\langle \ , \rangle : \bar{\Gamma} \times \bar{\Gamma} \to \mathbb{Z}\) defined in Section 2.

Proposition 4.2. The pairings \(\langle \ , \rangle\) and \(\text{ord}_p \circ [\ , ]\) are equal.

Proof. See [M, Th. 7.6].

It follows that \(\text{ord}_p \circ [\ , ]\) is positive definite, so that the map
\[
j : \bar{\Gamma} \to \mathcal{N} \otimes \mathbb{Q}_p^\times
\]
induced by \([\ , ]\) is injective and has discrete image. Set \(\Lambda := j(\bar{\Gamma})\). Given a divisor \(D\) of degree-zero on \(\mathcal{X}(\mathbb{C}_p) = \Gamma \backslash \mathcal{H}_p\), let \(\tilde{D}\) denote an arbitrary lift to a degree-zero divisor on \(\mathcal{H}_p\). The automorphy factor \(\phi_D\) depends on the choice of the lift \(\tilde{D}\), but its image in \((\mathcal{N} \otimes \mathbb{C}_p^\times)/\Lambda\) depends only on \(D\). Thus, the assignment \(D \mapsto \phi_D\) gives a well-defined map from \(\text{Div}^0(\mathcal{X}(\mathbb{C}_p))\) to \((\mathcal{N} \otimes \mathbb{C}_p^\times)/\Lambda\).

Proposition 4.3. The map \(\text{Div}^0(\mathcal{X}(\mathbb{C}_p)) \to (\mathcal{N} \otimes \mathbb{C}_p^\times)/\Lambda\) defined above is trivial on the group of principal divisors and induces a Hecke-equivariant isomorphism from the \(\mathbb{C}_p\)-points of the jacobian \(\mathcal{J}\) of \(\mathcal{X}\) to \((\mathcal{N} \otimes \mathbb{C}_p^\times)/\Lambda\).

Proof. See [GvdP, VI.2 and VII.4] and also [BC, Ch. III].

Let
\[
\Phi : \mathcal{N} \otimes \mathbb{C}_p^\times \to \mathcal{J}(\mathbb{C}_p)
\]
stand for the map induced by (the inverse of) the isomorphism defined in Proposition 4.3.

**Modular parametrizations, II.** The map $\eta_f : \mathcal{N} \to \mathbb{Z}$ defined in Section 2 induces a map

$$\eta_f \otimes \text{id} : \mathcal{N} \otimes \mathbb{C}_{p}^\times \to \mathbb{C}_{p}^\times.$$  

The Jacquet-Langlands correspondence [JL] implies that the quotient abelian variety $\eta_f J$ is an elliptic curve $\mathbb{Q}$-isogenous to $E$. From now on, we assume that $E = \eta_f J$ is the strong Weil curve for the parametrization by the Shimura curve $X$. By an abuse of notation, we denote by $\eta_f$ also the surjective map

$$J(\mathbb{C}_p) \to E(\mathbb{C}_p)$$

induced by $\eta_f$.

Let $\Lambda^f$ be the submodule of $\Lambda$ on which $\mathbb{T}$ acts via the character $\phi_f$.

**Proposition 4.4.** The kernel $q^\mathbb{Z}$ of $\Phi_{\text{Tate}}$ is canonically equal to the module $\Lambda^f$, and the diagram

$$
\begin{array}{c}
0 \longrightarrow \Lambda^f \longrightarrow \mathcal{N} \otimes \mathbb{C}_{p}^\times \longrightarrow \mathcal{J}(\mathbb{C}_p) \longrightarrow 0 \\
\downarrow \eta_f \quad \downarrow \eta_f \otimes \text{id} \quad \downarrow \eta_f \quad \downarrow \eta_f \\
0 \longrightarrow \Lambda \longrightarrow \mathcal{N} \otimes \mathbb{C}_{p}^\times \longrightarrow \mathcal{J}(\mathbb{C}_p) \longrightarrow 0
\end{array}
$$

is Hecke-equivariant and commutes up to sign.

**Proof.** The rightmost square in the above diagram is a consequence of Proposition 4.3, combined with Theorem 4.1 and the fact that $f$ is split-multiplicative at $p$. In order to obtain the leftmost square, it is enough to prove that the kernel of $\Phi_{\text{Tate}}$ is equal to $\Lambda^f$. Note that the target $\mathbb{C}_{p}^\times = \mathcal{N} \otimes \mathbb{C}_{p}^\times$ of the map $\eta_f \otimes \text{id}$ is naturally a submodule of $\mathcal{N} \otimes \mathbb{C}_{p}^\times$, since the quotient of $\mathcal{N}$ by $\mathcal{N}^f$ is torsion free. By definition, $E(\mathbb{C}_p)$ may similarly be viewed as an abelian subvariety of $\mathcal{J}(\mathbb{C}_p)$. It follows that $\Phi_{\text{Tate}}$ can be described as the restriction of $\Phi$ to $\mathbb{C}_{p}^\times$. In particular, $\ker(\Phi_{\text{Tate}})$ is equal to $\Lambda \cap \mathbb{C}_{p}^\times$. In turn, this last module is equal to $\Lambda^f$.

**Corollary 4.5.** The integer $\hat{c}_p = |\langle e^f, e_f \rangle|$ (introduced in Lemma 3.3) is equal to $c_p$.

**Proof.** Working through the definition of the maps in the diagram of Proposition 4.4 shows that $|\langle e^f, e_f \rangle|$ is equal to $q^\pm 1$. The claim follows from Proposition 4.2.

**5. $p$-adic Shintani cycles and special values of complex $L$-functions.** Let $P_0 = (R_0, \xi_0) \pmod{B^\times}$ be a Gross point of conductor $c$. The point $P_0$ determines a $p$-adic cycle $c(P_0) \in \mathbb{G}$ in the following way. By strong approximation, we may assume that the representative $(R_0, \xi_0)$ for $P_0$ is such that the oriented orders $R_0[1/p]$ and
$R[1/p]$ are equal. Thus, $\xi_0$ induces an embedding of $\mathcal{O}[1/p]$ into $R[1/p]$, which we still denote by $\xi_0$. The image by $\xi_0$ of a fundamental $p$-unit in $\mathcal{O}[1/p]$, having norm of even $p$-adic valuation, determines an element $\gamma = \gamma(P_0)$ of $\Gamma$. This element is well defined up to conjugation and up to inversion, and up to multiplication by the image of torsion elements of $\mathcal{O}^\times$.

More explicitly, write $k$ for the order of $\sigma_p$ in Pic($\mathcal{O}$) (where $\sigma_p$ is as in Lemma 3.1), and set $p^k = (v)$ with $v \in \mathcal{O}$. Let $i$ be $1$ (respectively, $2$) if $k$ is even (respectively, odd). Then $\gamma$ is the image of $\xi_0(v)i$ in $\Gamma$.

**Definition.** The $p$-adic Shintani cycle $\epsilon = \epsilon(P_0)$ attached to $P_0$ is the natural image of $\gamma$ in $\Gamma$.

This terminology is justified in Remark 5.4 below. Observe that $\epsilon$ is well defined up to sign.

Denote by $\mathbb{Z}[\mathcal{E}(\mathcal{S})]_{sp}$ the maximal torsion-free quotient of $\mathbb{Z}[\mathcal{E}(\mathcal{S})]/(w+1)\mathbb{Z}[\mathcal{E}(\mathcal{S})]$, where $w$ is any element of $\Gamma_+ - \Gamma$. Recall the element $\tilde{\eta}_f \in \hat{\Gamma}$ defined in the proof of Lemma 3.3, mapping to $\eta_f$ by the natural projection $\hat{\Gamma} \to \Gamma$. The next lemma relates the $p$-adic cycle $\epsilon$ to the image in $N_{sp}$ of the Gross point $P_0$.

**Lemma 5.1.** The natural images in $\mathbb{Z}[\mathcal{E}(\mathcal{S})]_{sp}$ of $\epsilon$ and $\sum_{\sigma \in \Sigma} \iota P_0^{\sigma}$ are equal. In particular, $\eta_f \epsilon$ is equal to the image of $\sum_{\sigma \in \Sigma} \iota (\tilde{\eta}_f P_0^{\sigma})$ in $\mathbb{Z}[\mathcal{E}(\mathcal{S})]$.

**Proof.** (In order to visualize the geometric content of this proof, the reader may find it helpful to refer to Figure 1 in Section 3.) Set $P_i := \sigma_p^i P_0$, for $i = 0, \ldots, k - 1$. By Lemma 3.1(1) and the definition of the action of $U_p$ on the Bruhat-Tits tree, we can fix representatives $(\tilde{e}_i, \xi_0)$ for the Gross points $P_i$ so that the $\tilde{e}_i$ are consecutive oriented edges of $\overline{T}$. With notation as at the beginning of this section, let $\gamma_{+} \in \Gamma_+$ be the image of $\xi_0(v)$. Thus, $\gamma = \gamma_{+}$. Call $v_0$ the origin of $\tilde{e}_0$. If $i = 1$, the even vertex of the edge $\tilde{e}_{k-1}$ is equal to $\gamma v_0$. If $i = 2$, that is, $\gamma_{+}$ belongs to $\Gamma_+ - \Gamma$, then

$$\tilde{e}_0, \ldots, \tilde{e}_{k-1}, \gamma_{+} \tilde{e}_0, \ldots, \gamma_{+} \tilde{e}_{k-1}$$

is a sequence of consecutive oriented edges, and the even vertex of $\gamma_{+} \tilde{e}_{k-1}$ is equal to $\gamma v_0$. Note that $\sum_{\sigma \in \Sigma} \iota P_0^{\sigma}$ is equal in $\mathbb{Z}[\mathcal{E}(\mathcal{S}_+)]$ to $\tilde{e}_0 + \tilde{e}_1 + \cdots + \tilde{e}_{k-1}$ if $i = 1$ and equal to

$$\tilde{e}_0 + \tilde{e}_1 + \cdots + \tilde{e}_{k-1} + \gamma_{+} \tilde{e}_0 + \gamma_{+} \tilde{e}_1 + \cdots + \gamma_{+} \tilde{e}_{k-1}$$

if $i = 2$. Denote by $e_i$ the unoriented edge of $\overline{T}$ corresponding to $\tilde{e}_i$, and let $w$ be any element of $\Gamma_+ - \Gamma$. By the definition of the bijection $\kappa$ of Lemma 2.2, the following equalities hold in $\mathbb{Z}[\mathcal{E}(\mathcal{S})]$:

$$\kappa^{-1} (\tilde{e}_0 + \cdots + \tilde{e}_{k-1}) = e_0 + we_1 + \cdots + e_{k-2} + we_{k-1} \quad \text{if } i = 1,$$

$$\kappa^{-1} (\tilde{e}_0 + \cdots + \tilde{e}_{k-1} + \gamma_{+} \tilde{e}_0 + \gamma_{+} \tilde{e}_1 + \cdots + \gamma_{+} \tilde{e}_{k-1}) = e_0 + we_1 + \cdots + e_{k-1} + w(\gamma_{+} e_0 + (\gamma_{+} e_1) + \cdots + w(\gamma_{+} e_{k-1}) \quad \text{if } i = 2.$$
account the fact that \( w \) acts as \(-1\) on this module, gives in both cases path(v_0, γv_0).

The next proposition elucidates the relation between the \( p \)-adic Shintani cycle defined above and the special values of the complex \( L \)-function of \( E/K \). Following the notation of Section 3, fix Gross points \( P_0 = P_0^1, \ldots, P_0^h \) that are representatives for the \( \Sigma \)-orbits of the Gross points of conductor \( c \), and list the elements of \( \omega_{\text{zelt}} \) so that \([\delta_i P_0^1] = [P_0^i] \), where \([P_0^i]\) denotes the \( \Sigma \)-orbit of \( P_0^i \). As above, the Gross point \( P_0^i \) determines a \( p \)-adic Shintani cycle \( c_i \in \bar{\omega}_{\text{iam}} \), with \( c_1 = c \). Given a complex character \( \chi : \Delta \to \mathbb{C}^\times \) of \( \Delta \), set

\[
\epsilon_H := \sum_{i=1}^h c_i \otimes \delta_i^{-1} \in \tilde{\Gamma} \otimes \mathbb{Z}[\Delta],
\]

\[
\epsilon_{K,\chi} := \chi(\epsilon_H) = \sum_{i=1}^h c_i \otimes \chi(\delta_i)^{-1} \in \tilde{\Gamma} \otimes \mathbb{Z}[\chi].
\]

If \( \chi \) is the trivial character, we also write \( \epsilon_K \) as a shorthand term for \( \epsilon_{K,\chi} \). Extend the pairing \( \langle , \rangle \) on \( \bar{\omega}_{\text{iam}} \) to a hermitian pairing on \( \tilde{\Gamma} \otimes \mathbb{Z}[\chi] \).

**Proposition 5.2.** Suppose that \( \chi \) is primitive. The following equality holds:

\[
\langle \eta_f \epsilon_{K,\chi}, \epsilon_{K,\chi} \rangle = L(E/K, \chi, 1) \frac{\Omega_f}{\sqrt{d}} \cdot (\sigma u)^2 \cdot n_f.
\]

**Proof.** In view of Lemma 5.1, this is simply a restatement of the results of [Gr] and [Dag].

Recall the maps \( j : \tilde{\Gamma} \to \mathbb{N} \otimes \mathbb{Q}_p^\times \) and \( \eta_f \otimes \text{id} : \mathbb{N} \otimes \mathbb{C}_p^\times \to \mathbb{C}_p^\times \) defined in Section 4. By abuse of notation, we denote the maps obtained by extending scalars to \( \mathbb{Z}[\chi] \) in the same way.

**Corollary 5.3.** The equality

\[
(\eta_f \otimes \text{id})(j(\epsilon_{K,\chi})) = q \otimes \rho
\]

holds in \( \mathbb{Q}_p^\times \otimes \mathbb{Z}[\chi] \), where \( \rho \in \mathbb{Z}[\chi] \) satisfies

\[
|\rho|^2 = \frac{L(E/K, \chi, 1)}{\Omega_f} \sqrt{d} \cdot (\sigma u)^2 \cdot n_f.
\]

**Proof.** By Proposition 4.4 combined with the definition of \( \eta_f \) given in Section 2, \( \rho \) is equal to \( \langle \epsilon_{K,\chi}, e^f \rangle \in \mathbb{Z}[\chi] \). Hence

\[
|\rho|^2 = \langle \epsilon_{K,\chi}, e^f \rangle \langle e^f, \epsilon_{K,\chi} \rangle
\]

\[
= \langle \eta_f \epsilon_{K,\chi}, \epsilon_{K,\chi} \rangle.
\]

The claim follows from Proposition 5.2.
**6. \( p \)-adic Shintani cycles and derivatives of \( p \)-adic \( L \)-functions.** Let \( P_0 \) be a Gross point of conductor \( c \). In Section 5, we attached to \( P_0 \) a \( p \)-adic cycle \( c \in \mathcal{G} \), and proved in Proposition 5.2 that \( c \) is related to the special values of the complex \( L \)-function of \( E/K \). Our main result (Theorem 6.1 below) shows that \( c \) is also related to the first derivative of the \( p \)-adic \( L \)-function defined in Section 3. By combining these results, we obtain Theorem 1.1.

Write \( \bar{j} \) for the composite map

\[
\mathcal{G} \xrightarrow{\bar{j}} \mathcal{N} \otimes \mathcal{Q}_p^\times \to \mathcal{N}_{sp} \otimes \mathcal{Q}_p^\times \to \mathcal{N}_{sp} \otimes G_\infty,
\]

where the second map is induced by the natural projection of \( \mathcal{N} \) onto \( \mathcal{N}_{sp} \), and the third map is induced by \( \text{rec}_p : \mathcal{Q}_p^\times \to G_\infty \). Our main result is the following.

**Theorem 6.1.** The following equality holds up to sign in \( \mathcal{N}_{sp} \otimes G_\infty \):

\[
\mathcal{L}'_{p}(\mathcal{N}_{sp}/P_0) = \bar{j}(c).
\]

Recall the definition of the elements \( \epsilon_H \) and \( \epsilon_K \) given in Section 5. By Lemma 3.8, we obtain the following corollary directly.

**Corollary 6.2.** (i) The following equality holds up to sign in \( \mathcal{N}_{sp} \otimes \mathbb{Z}[\Delta] \otimes G_\infty \):

\[
\mathcal{L}'_{p}(\mathcal{N}_{sp}/H) = \bar{j}(\epsilon_H).
\]

(ii) The following equality holds up to sign in \( \mathcal{N}_{sp} \otimes G_\infty \):

\[
\mathcal{L}'_{p}(\mathcal{N}_{sp}/K) = \bar{j}(\epsilon_K).
\]

By applying the operator \( \eta_f \) to both sides of the equalities of Corollary 6.2, and using Corollary 4.5 and the definitions of the \( p \)-adic \( L \)-functions attached to \( \mathcal{N}_{sp} \) and \( E \), we find the following.

**Corollary 6.3.** (i) The following equality holds up to sign in \( \mathbb{Z}[\Delta] \otimes G_\infty \):

\[
c_{p}\mathcal{L}'_{p}(E/H) = \bar{j}(\eta_f \epsilon_H).
\]
The following equality holds up to sign in $G_\infty$:

$$c_p \mathcal{L}'_p(E/K) = j(\eta_f \epsilon_K).$$

**Proof of Theorem 1.1.** Combine Corollary 6.3 with Corollary 5.3.

By combining Corollary 6.3 with Corollary 5.3, we also obtain the following generalization of Theorem 1.1. Let $\mathcal{L}'_p(E/K, \chi)$ stand for the element $\chi(\mathcal{L}'_p(E/H))$ of $G_\infty \otimes \mathbb{Z}[\chi]$.

**Theorem 6.4.** Suppose that $\chi$ is primitive. The following equalities hold up to sign:

$$c_p \mathcal{L}'_p(E/K, \chi) = \text{rec}_p(q) \otimes \rho \quad \text{in } G_\infty \otimes \mathbb{Z}[\chi]$$

and

$$\mathcal{L}'_p(E/K, \chi) = \frac{\text{rec}_p(q)}{\text{ord}_p(q)} \otimes \rho \quad \text{in } G_\infty \otimes \mathbb{Q}[\chi],$$

where

$$|\rho|^2 = \frac{L(E/K, \chi, 1)}{\Omega_f} \cdot d^{1/2} u^2 n_f.$$ 

**Corollary 6.5.** The derivative $\mathcal{L}'_p(E/K, \chi)$ is nonzero in $G_\infty \otimes \mathbb{Q}[\chi]$ if and only if the classical special value $L(E/K, \chi, 1)$ is nonzero.

**Proof.** By Theorem 6.4, one is reduced to showing that $\text{rec}_p(q)$ is a nontorsion element of $G_\infty$; that is, $q^{p-1}$ does not belong to the kernel of the reciprocity map. But elements in this kernel are algebraic over $\mathbb{Q}$, and $q$ is known to be transcendental by a result of Barré-Sirieix, Diaz, Gramain, and Philibert [B-SDGP].

**Remark 6.6.** Theorem 1.1 was conjectured in [BD1, Sec. 5.1] in a slightly different form. We conclude this section by studying the compatibility of Theorem 1.1 (and its generalization Theorem 6.4) with the conjectures of [BD1]. For simplicity, assume throughout this remark that the elliptic curve $E$ is semistable so that $N$ is squarefree, and that $E$ is isolated in its isogeny class so that the action of $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on the $\ell$-torsion points of $E$ is irreducible for all primes $\ell$.

Let $p_1 \cdots p_n q_1 \cdots q_n$ be a prime factorization of the squarefree integer $pN^-$, with $p_1 = p$. Denote by $X_1$ the Shimura curve $X$, and by $X_{n+1}$ the classical modular curve $X_0(N)$. For $i = 2, \ldots, n$, denote by $X_i$ the Shimura curve associated with an Eichler order of level $N^+ p_1 \cdots p_{i-1} q_1 \cdots q_{i-1}$ in the indefinite quaternion algebra of discriminant $p_1 \cdots p_n q_1 \cdots q_n$. Since $E$ is modular, the Jacquet-Langlands correspondence [JL] implies that $E$ is parametrized by the jacobian $J_i$ of the curve $X_i$, $i = 1, \ldots, n + 1$. Let

$$\phi_i : J_i \to E$$

be the strong Weil parametrization of $E$ by $J_i$. Thus, the morphism $\phi_i$ has connected kernel, and its dual $\phi_i^\vee : E \to J_i$ is injective. The endomorphism $\phi_i \circ \phi_i^\vee$ of $E$ is
multiplication by an integer $d_{X_i}$, called the degree of the modular parametrization of $E$ by the Shimura curve $X_i$.

If $\ell \mid N$, denote by $c_{\ell}$ the order of the group of connected components of $E$ at $\ell$.

**Theorem 6.7 (Ribet-Takahashi).** Under our assumptions

(i) \[
\frac{d_{X_0(N)}}{d_X} = c_{p_1} \cdots c_{p_n} c_{q_1} \cdots c_{q_n}.
\]

(ii) \[
\{e^f, e^{-f}\} = d_X c_{\ell}.
\]

**Proof.** Part (i) follows from Theorem 1 of [RT]. Part (ii) follows from Section 2 of [RT]. The results of [RT] exclude the case where $N^+$ is prime, but a forthcoming paper of Takahashi will deal with this case as well.

By combining Theorem 6.7 with the relation $\Omega_f = d_{X_0(N)} \cdot \Omega_E$, where $\Omega_E$ is the complex period of $E$, we find that the formula of Theorem 1.1 (and likewise for Theorem 6.4) becomes

\[
\mathcal{L}_p'(E/K) = \frac{\text{rec}_p(q)}{\text{ord}_p(q)} \sqrt{L(E/K, 1) \Omega_E^{-1} \cdot d^{1/2} \prod_{\ell \mid N} c_{\ell}^{-1}},
\]

which is the same as Conjecture 5.3 of [BD1].

**7. Proof of Theorem 6.1.** First, we give an explicit description of certain group actions on the $p$-adic upper half plane and on the Bruhat-Tits tree depending on our choice of a Gross point $P_0$ of conductor $c$. Then, we compute the value $j(c)$, for $c$ as in Sections 5 and 6.

**I. Group actions on $\mathfrak{H}_p$ and $\mathcal{T}$.** Let $K_p := K \otimes \mathbb{Q}_p$. Our choice of a prime $p$ above $p$ determines an identification of $K_p = K_p \times K_p^{1/p}$.

As in Section 5, choose a representative $(R_0, \xi_0)$ for the Gross point $P_0$ such that $R_0[1/p]$ and $R[1/p]$ are equal. Let $(\tilde{e}_0, \xi_0)$ be a pair corresponding to $P_0$, and denote by $v_0$ the origin of $\tilde{e}_0$. Set $R_0 := R_0 \otimes \mathbb{Z}_p$, and let $R_{0,p}$ be the maximal order of $B_p$ corresponding to $v_0$. Recall the isomorphism

\[
\psi : B_p \to M_2(\mathbb{Q}_p)
\]

fixed in Section 4. We may, and do from now on, choose $\psi$ so that

(i) $\psi$ maps $R_{0,p}$ onto $M_2(\mathbb{Z}_p)$;

(ii) $\psi \circ \xi_0$ maps $(x, y) \in K_p = Q_p \times Q_p$ to the diagonal matrix \[
\begin{pmatrix}
\chi & 0 \\
0 & \chi
\end{pmatrix}
\]

Condition (i) allows us to identify $\mathcal{T} = \mathbb{Q}_p^\times \backslash B_p^\times$ with $\text{PGL}_2(\mathbb{Z}_p) \backslash \text{PGL}_2(\mathbb{Q}_p)$. Viewing $K_p^\times$ as a subgroup of $\text{GL}_2(\mathbb{Q}_p)$ thanks to the embedding $\psi \circ \xi_0$ yields actions of $K_p^\times$ on $\mathfrak{H}_p$ and on $\mathcal{T} = \text{PGL}_2(\mathbb{Z}_p) \backslash \text{PGL}_2(\mathbb{Q}_p)$, factoring through $K_p^\times / Q_p^\times$. 
Identify this last group with $Q_p^{\times}$ by mapping a pair $(x, y)$ modulo $Q_p^{\times}$ to $xy^{-1}$. Under this identification, an element $x$ of $Q_p^{\times}$ acts on $\mathcal{H}_p$ as multiplication by $x$, and on $\mathcal{T}$ as conjugation by the matrix \[
abla 0 \choose 0 1\].

Recall the element $v \in \mathcal{O} \subset K_p^{\times}$ defined in Section 5 by $p^k = (v)$. Identify, as above, $v$ with an element $w$ of $Q_p^{\times}$. Note that $w$ is equal to $p^k$ times a $p$-adic unit. Set $\tilde{G}_\infty := Q_p^{\times} = p^Z \times Z_p^{\times}$. Define the quotients of $\tilde{G}_\infty$.

$$\tilde{\Sigma} := Q_p^{\times} / Z_p^{\times} = p^Z, \quad \tilde{G}_n := p^Z \times (Z_p/p^nZ_p)^{\times}, \ n \geq 1.$$  

To simplify slightly the computation, assume from now on that $\mathcal{O}^{\times} = \{\pm 1\}$. If $\mathcal{O}^{\times} \neq \{\pm 1\}$, then $K$ has discriminant $-3$ or $-4$, and the exact sequences below have to be modified to account for the nontrivial units of $\mathcal{O}$. The computations in this case follow closely those presented in the paper.) Class field theory yields the exact sequence

$$0 \to \langle w \rangle \to \tilde{G}_\infty \xrightarrow{rec_p} G_\infty \to 0$$

and the induced sequences

$$0 \to \langle w \rangle \to \tilde{\Sigma} \to \Sigma \to 0, \quad 0 \to \langle w \rangle \to \tilde{G}_n \to G_n \to 0.$$

For $n \geq 0$, denote by $\mathcal{Z}_p^{(n)} \subset \tilde{G}_\infty$ the subgroup of elements of $\mathcal{Z}_p^{\times}$ that are congruent to one modulo $p^n$.

**Definition.** We say that a vertex $v$ of $\mathcal{T}$ has level $n$, and write $\ell(v) = n$, if the stabilizer of $v$ for the action of $\tilde{G}_\infty$ is equal to $\mathcal{Z}_p^{(n)}$. Likewise, we say that an edge $e$ of $\mathcal{T}$ has level $n$, and write $\ell(e) = n$, if the stabilizer of $e$ for the action of $\tilde{G}_\infty$ is $\mathcal{Z}_p^{(n)}$.

Note that the group $\tilde{G}_n$ ($\tilde{\Sigma}$ if $n = 0$) acts simply transitively on the vertices and edges of level $n$. By definition of the action of $\tilde{G}_\infty$ on $\mathcal{T}$, $v_0$ is a vertex of level 0. Thus, the set of vertices of level 0 is equal to the $\tilde{\Sigma}$-orbit of $v_0$. More generally, the set of vertices of level $n$ can be described as the $\tilde{G}_n$-orbit of a vertex $v_n$ whose distance from $v_0$ is $n$ and whose distance from all the other vertices in the orbit $\Delta v_0$ is $> n$.

By using the standard coordinate, identify $\mathcal{P}^1(\mathbb{C}_p)$ with $\mathbb{C}_p \cup \{\infty\}$ and $\mathcal{H}_p$ with $\mathcal{P}^1(\mathbb{C}_p) - \mathcal{P}^1(\mathbb{Q}_p)$. In particular, view $0$ and $\infty$ as elements of $\mathcal{P}^1(\mathbb{Q}_p)$. Recall the element $\gamma = \gamma(P_0)$ of $\Gamma$ defined in Section 5. Since the reduced norm of $\gamma$ has positive valuation, our choice of the isomorphism $\psi$ yields

$$\lim_{n \to +\infty} \gamma^n z = 0, \quad \lim_{n \to -\infty} \gamma^n z = \infty$$

for all $z \in \mathcal{H}_p$. Note also that 0 and $\infty$ are the fixed points for the action of $\tilde{G}_\infty$ on $\mathcal{P}^1(\mathbb{C}_p)$.

Let $\mathcal{H}_p(\mathbb{Q}_{p^2}) = \mathbb{Q}_{p^2} - \mathbb{Q}_p$ be the $\mathbb{Q}_{p^2}$-points of the $p$-adic upper half plane. Define the reduction map

$$r : \mathcal{H}_p(\mathbb{Q}_{p^2}) \to \mathcal{V}(\mathcal{T})$$
as follows. Given \( z \in \mathfrak{H}_p(\mathbb{Q}_p^2) \), let \( \mathcal{O}_z \) denote the stabilizer of \( z \) in \( \text{GL}_2(\mathbb{Q}_p) \), together with the zero matrix. Then \( \mathcal{O}_z \) is a field isomorphic to \( \mathbb{Q}_p^2 \), and this gives rise to an embedding of \( \mathbb{Q}_p^2 \) in \( \text{M}_2(\mathbb{Q}_p) \) (well defined up to an isomorphism of \( \mathbb{Q}_p^2 \)). Write \( \mathbb{Z}_p^2 \) for the ring of integers of \( \mathbb{Q}_p^2 \), and let \( S \) be the unique maximal order of \( \text{M}_2(\mathbb{Q}_p) \) containing the image of \( \mathbb{Z}_p^2 \) by the above embedding. We have \( r(z) = S \). (See also [BD2, Sec. 1].)

**Lemma 7.1.** (1) The reduction map \( r \) is \( \text{GL}_2(\mathbb{Q}_p) \)-equivariant. In particular, \( r \) is equivariant for the group actions defined above.

(2) Write \( \mathbb{Z}_p^2 = \mathbb{Z}_p \alpha + \mathbb{Z}_p \). We have \( r^{-1}(v_0) = \mathbb{Z}_p \alpha + \mathbb{Z}_p^2 \).

(3) If \( z_1 \) and \( z_2 \) are mapped by \( r \) to adjacent vertices of respective levels \( n \) and \( n+1 \), then \( z_1 z_2^{-1} \equiv 1 \mod p^n \).

**Proof.** (1) Let \( z \) be an element of \( \mathfrak{H}_p(\mathbb{Q}_p^2) \), and let \( B \) be a matrix in \( \text{GL}_2(\mathbb{Q}_p) \). If \( f : \mathbb{Q}_p^2 \to \text{M}_2(\mathbb{Q}_p) \) is an embedding fixing \( z \), then \( BfB^{-1} \) is an embedding fixing \( Bz \). Suppose that \( S \) is the maximal ideal containing \( f(\mathbb{Z}_p^2) \). Then \( BSB^{-1} = S \ast B^{-1} \) is the maximal ideal containing the image of \( \mathbb{Z}_p^2 \) by \( BfB^{-1} \). Thus, \( r(Bz) = S \ast B^{-1} \), as was to be shown.

(2) Assume that \( p \) is greater than 2. Then, we may assume that \( \alpha = \sqrt{\nu} \), where the integer \( \nu \) is not a square modulo \( p \). (The case where \( p = 2 \) can be dealt with in a similar way—e.g., by taking \( \alpha = (1 + \sqrt{-3})/2 \).) A direct computation shows that

\[
\mathcal{O}_\sqrt{\nu} = \left\{ \begin{pmatrix} b & a \nu \\ a & b \end{pmatrix} : a, b \in \mathbb{Q}_p \right\}.
\]

Mapping the above matrix to \( a\sqrt{\nu} + b \) yields an isomorphism of \( \mathcal{O}_\sqrt{\nu} \) onto \( \mathbb{Q}_p^2 \). Thus, \( r(\sqrt{\nu}) \) is equal to \( v_0 = M_2(\mathbb{Z}_p) \). Given \( z = a\sqrt{\nu} + b \in \mathfrak{H}_p(\mathbb{Q}_p^2) \), we have \( z = B \sqrt{\nu} \), where \( B \) is the matrix \( \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} \). By (1),

\[
r(z) = BM_2(\mathbb{Z}_p)B^{-1}.
\]

But \( BM_2(\mathbb{Z}_p)B^{-1} = M_2(\mathbb{Z}_p) \) if and only if \( B \) belongs to \( GL_2(\mathbb{Z}_p) \), that is, \( a \) belongs to \( \mathbb{Z}_p^\times \).

(3) Set \( r(z_1) = v_1 \) and \( r(z_2) = v_2 \). The edge joining \( v_1 \) to \( v_2 \) has level \( n+1 \). Since \( \tilde{G}_\infty = \mathbb{Q}_p^\times \) acts transitively on the edges of level \( n+1 \), there is \( g \in \mathbb{Q}_p^\times \) such that \( g v_1 \) and \( g v_2 \) have distance from \( v_0 \) equal to \( n \) and \( n+1 \), respectively. With notation as in the proof of (2) of this proposition, write \( g z_i = a_i \sqrt{\nu} + b_i, i = 1, 2 \), where \( a_i, b_i \in \mathbb{Z}_p \), \( \gcd(a_i, b_i) = 1 \), and \( p^n \parallel a_1, p^{n+1} \parallel a_2 \). Thus, the vertex \( g v_1 \) is represented by the matrix

\[
A_i = \begin{pmatrix} a_i & b_i \\ 0 & 1 \end{pmatrix}.
\]

Our assumption on \( g v_1 \) and \( g v_2 \) implies that the column \( \begin{pmatrix} b_2 \\ 1 \end{pmatrix} \) of \( A_2 \) is a \( \mathbb{Z}_p \)-linear
combination of the columns of $A_1$. It follows that $b_1 \equiv b_2 \pmod{p^n}$, and hence
\[ z_1 z_2^{-1} = g z_1 (g z_2)^{-1} \equiv 1 \pmod{p^n}. \]

II. The calculation. Given $\delta \in \Gamma$, write as usual $\bar{\delta}$ for the natural image of $\delta$ in $\tilde{\Gamma}$. We now compute explicitly the value of $j(c)(\bar{\delta}) = [c, \bar{\delta}]$, for $\delta \in \Gamma$. We begin with the following lemma.

**Lemma 7.2.** Given $\delta \in \omega_{\natural \gamma \text{amam}}$, we have
\[ j(c)(\bar{\delta}) = \prod_{\epsilon \in \bar{\gamma}} \epsilon \delta \cdot z_0 \cdot \epsilon \bar{\gamma}a, \]
where $z_0$ is any element in $\mathcal{H}_p$, and $\bar{\gamma}$ is any set of representatives for $\langle \gamma \rangle \setminus \Gamma$.

**Proof.** (Cf. [M, Th. 2.8]). Let $\mathcal{F}'$ be any set of representatives for $\Gamma / \langle \gamma \rangle$. In view of the formulae (4), for any $z_0$ and $a$ in $\mathcal{H}_p$ we have the chain of equalities
\[
j(c)(\bar{\delta}) = \prod_{\epsilon \in \mathcal{F}'} \frac{z_0 - \epsilon a}{z_0 - \epsilon \gamma a} \cdot \frac{\delta z_0 - \epsilon \gamma a}{\delta z_0 - \epsilon a} = \prod_{\epsilon \in \mathcal{F}'} \lim_{N \to +\infty} \frac{z_0 - \epsilon \gamma^{-N} a}{z_0 - \epsilon \gamma^{-N+1} a} \cdot \frac{\delta z_0 - \epsilon \gamma^{-N+1} a}{\delta z_0 - \epsilon \gamma^{-N} a} = \prod_{\epsilon \in \mathcal{F}'} \frac{z_0 - \epsilon \infty}{z_0 - \epsilon 0} \cdot \frac{\delta z_0 - \epsilon 0}{\delta z_0 - \epsilon \infty} = \prod_{\epsilon \in \mathcal{F}'} \frac{\epsilon^{-1} \delta z_0}{\epsilon^{-1} z_0}.
\]

Note that $(\mathcal{F}')^{-1}$ is a set of representatives for $\langle \gamma \rangle \setminus \Gamma$, and any set of representatives for $\langle \gamma \rangle \setminus \Gamma$ can be obtained in this way. The claim follows.

**Lemma 7.3.** Let $d$ be an edge of $\tilde{\Gamma}$, let $n$ be a positive integer, and let $\mathcal{F}$ be a set of representatives for $\langle \gamma \rangle \setminus \Gamma$. Then the set $\{ \epsilon \in \mathcal{F} : \ell(\epsilon d) \leq n \}$ is finite.

**Proof.** If $\{\epsilon_i\}$ is a sequence of distinct elements of $\mathcal{F}$ such that $\ell(\epsilon_i d) \leq n$, we can find integers $k_i$ such that $\gamma^{k_i} \epsilon_i d$ describes only finitely many edges. This contradicts the discreteness of $\Gamma$.

We say that two elements of $\tilde{\Gamma}$ are **linearly independent** if they generate a rank-two free abelian subgroup of $\tilde{\Gamma}$.

**Proposition 7.4.** (1) Suppose that $c$ and $\bar{\delta}$ are linearly independent in $\tilde{\Gamma}$. There exists a set $\mathcal{F}$ of representatives for $\langle \gamma \rangle \setminus \Gamma$ such that if $\epsilon$ belongs to $\mathcal{F}$, then all the elements of the coset $\epsilon (\delta)$ belong to $\mathcal{F}$.
(2) There exists a set $\mathcal{F} = \mathcal{F}_0 \bigsqcup \mathcal{F}_1$ of representatives for $\langle \gamma \rangle \setminus \Gamma$ such that

(i) the set $\mathcal{F}_0$ contains a finite number of elements that are mapped by the isomorphism $\psi$ to diagonal matrices of $\text{PGL}_2(\mathbb{Q}_p)$;

(ii) if $\epsilon$ belongs to $\mathcal{F}_1$, then all the elements of the coset $\epsilon \langle \gamma \rangle$ belong to $\mathcal{F}_1$.

Proof (Cf. [M, Lemma 2.7]). (1) Consider a decomposition of $\Gamma$ as a disjoint union of double cosets

$$\Gamma = \bigsqcup_{\epsilon \in \mathcal{F}} \langle \gamma \rangle \epsilon \langle \delta \rangle.$$ 

We claim that we may take $\mathcal{F}_0$ to be $\{\epsilon \delta m : \epsilon \in \mathcal{F}, m \in \mathbb{Z}\}$. For, if $\epsilon \delta^m = \gamma^r \epsilon \delta^n$, we find $\delta^{m-n} = \epsilon^{-1} \gamma^r \epsilon$. Projecting this relation to $\mathcal{F}$ gives $m = n$.

(2) Consider a decomposition of $\Gamma$ as a disjoint union of double cosets

$$\Gamma = \bigsqcup_{\epsilon \in \mathcal{F}} \langle \gamma \rangle \epsilon \langle \gamma \rangle.$$ 

Define $\mathcal{F}_1$ to be the set of elements of $\Gamma$ of the form $\epsilon \gamma^m$, $m \in \mathbb{Z}$, where $\epsilon \in \mathcal{F}$ is such that $\langle \gamma \rangle \epsilon \gamma^m \neq \langle \gamma \rangle \epsilon \gamma^m$ whenever $m \neq n$. As for $\mathcal{F}_0$, we claim that it can be taken to be the set of elements $\epsilon \in \mathcal{F}$ that do not satisfy the above condition. In such a case, there is a relation $\gamma^r \epsilon \gamma^m = \epsilon \gamma^m$ for integers $r$ and $m \neq n$. Then, $\gamma^r = \epsilon \gamma^{m-n} \epsilon^{-1}$. By projecting this equality to $\mathcal{F}$, we see that $m-n = r$, and hence $\epsilon$ and $\gamma^r$ commute. Since $\gamma^r$ is mapped by $\psi$ to the diagonal matrix $\begin{pmatrix} w^r & 0 \\ 0 & 1 \end{pmatrix}$, where $\text{ord}_p(w) = k > 0$, a direct computation shows that $\epsilon$ is also diagonal (and thus commutes with $\gamma$). Now consider the group of all the diagonal matrices in $\psi(\Gamma)$. Since $\Gamma$ is discrete, this group is the product of a finite group by a cyclic group containing the group generated by $\gamma$. In conclusion, the set $\mathcal{F}_0$ is finite, and

$$\bigsqcup_{\epsilon \in \mathcal{F}_0} \langle \gamma \rangle \epsilon \langle \gamma \rangle = \bigsqcup_{\epsilon \in \mathcal{F}_0} \langle \gamma \rangle \epsilon.$$ 

The claim follows.

In the computation of $j(\epsilon)(\delta)$, we can assume that either

(I) $\epsilon$ and $\delta$ are linearly independent; or

(II) $\delta = \epsilon$.

(In fact, if the rank of $\mathcal{F}$ is greater than 1, it is enough to consider elements as in the first case, since the linear map $j(\epsilon)$ is completely determined by the values $j(\epsilon)(\delta)$, for $\epsilon$ and $\delta$ linearly independent.) In case (I), we use the notation $\mathcal{F}_1 := \mathcal{F}$, and the symbol $\mathcal{F}_1$ always refers to a choice of representatives for $\langle \gamma \rangle \setminus \Gamma$ as in Proposition 7.4(1). In case (II), the symbol $\mathcal{F} = \mathcal{F}_0 \bigsqcup \mathcal{F}_1$ stands for a choice of representatives as in Proposition 7.4(2).

**Lemma 7.5.** Let $\delta \in \mathcal{F}$ be as in case (I) or (II) above. Then, the images in $G_\infty$ by the reciprocity map of $j(\epsilon)(\delta)$ and $\prod_{\epsilon \in \mathcal{F}_1} \epsilon \delta z_0 / \epsilon z_0$ are equal.
Proof. In case (I), there is nothing to prove. In case (II), Proposition 7.4 combined with a direct computation shows that
\[ \prod_{\epsilon \in F_0} \frac{\epsilon Y Z_0}{\epsilon z_0} = w^{|F_0|}. \]
Since \( w \) is in the kernel of the reciprocity map, the claim follows.

By Lemma 7.5, we are now reduced to computing the product \( \prod_{\epsilon \in F_1} \epsilon \delta z_0 / \epsilon z_0 \), with \( \delta \) as in case (I) or (II).

We begin with some preliminary remarks. Fix an edge \( e \) of level equal to an odd integer \( n \), having \( v \) as its vertex of level \( n \). Moreover, assume that the distance of \( v \) from \( v_0 \) is also equal to \( n \). Note that the image in \( M \) of \( e \) is equal to the image in \( M \) of a Gross point of conductor \( cp^n \).

Given \( \tilde{\sigma} \in \tilde{G}_n \), define \( \mu_{\tilde{\sigma}} \) to be equal to 1 (respectively, \(-1\)) if \( \tilde{\sigma} v \) has odd (respectively, even) distance from \( v_0 \). If \( i = 1 \), observe that \( \mu_{\tilde{\sigma}} \) depends only on the image \( \tilde{\sigma} \) of \( \tilde{\sigma} \) in \( \Sigma \) under the projection induced by the reciprocity map; in this case, we write \( \mu_{\tilde{\sigma}} \) instead of \( \mu_{\tilde{\sigma}} \). If \( i = 2 \), then \( \mu_{\tilde{\sigma}} \) is constant on the elements \( \tilde{\sigma} \) that have the same image in \( \Sigma \) and \( p \)-adic valuation of the same parity; moreover, the values of \( \mu_{\tilde{\sigma}} \) corresponding to different parities are opposite. In this case, if \( \tilde{\sigma} \) projects in \( \Sigma \) to \( \tilde{\sigma} \) and \( \text{ord}_p(\tilde{\sigma}) \) is even, we let \( \mu_{\tilde{\sigma}} \) stand for \( \mu_{\tilde{\sigma}} \).

Given an edge \( d \) of \( \mathcal{F} \), and \( \tilde{\sigma} \in \tilde{G}_n \), write \( \tilde{\sigma} e \equiv d \) if the edge \( \tilde{\sigma} e \) is \( \mathcal{F}_1 \)-equivalent to \( d \), and \( \sigma e \approx d \) if the element \( \sigma e \) of \( M \) is \( \Gamma \)-equivalent to \( d \). If \( i = 1 \), the relation \( \tilde{\sigma} e \equiv d \) implies that \( \sigma e \approx d \). If \( i = 2 \), \( \tilde{\sigma} e \equiv d \) yields \( \sigma e \approx d \) when \( \text{ord}_p(\tilde{\sigma}) \) is even, and \( \sigma e \approx wd \), with \( w \in \Gamma_+ - \Gamma \), when \( \text{ord}_p(\tilde{\sigma}) \) is odd.

Recall that \( \omega_d \) denotes the order of the stabilizer in \( \Gamma \) of \( d \).

**Lemma 7.6.** (1) Suppose that \( i = 1 \). If the odd integer \( n \) is sufficiently large, the projection \( \tilde{G}_n \to G_n \) induces a \( \omega_d \)-to-1 map

\[ \{ \tilde{\sigma} \in \tilde{G}_n : \tilde{\sigma} e \equiv d \} \to \{ \sigma \in G_n : \sigma e \approx d \}. \]

(2) Suppose that \( i = 2 \). If the odd integer \( n \) is sufficiently large, the projection \( \tilde{G}_n \to G_n \) induces \( \omega_d \)-to-1 maps

\[ \{ \tilde{\sigma} \in \tilde{G}_n : \tilde{\sigma} e \equiv d, \text{ ord}_p(\tilde{\sigma}) \text{ even} \} \to \{ \sigma \in G_n : \sigma e \approx d \} \]

and

\[ \{ \tilde{\sigma} \in \tilde{G}_n : \tilde{\sigma} e \equiv d, \text{ ord}_p(\tilde{\sigma}) \text{ odd} \} \to \{ \sigma \in G_n : \sigma e \approx wd \}. \]

**Proof.** (1) Suppose that \( \tilde{\sigma} e \equiv d \) and \( \tilde{\sigma} e \equiv d \); that is, \( \tilde{\sigma} e = \epsilon_1 d \) and \( \tilde{\sigma} e = \epsilon_2 d \), for \( \epsilon_1 \) and \( \epsilon_2 \) in \( \mathcal{F}_1 \). If \( \tilde{\sigma}_1 \) and \( \tilde{\sigma}_2 \) have the same image in \( G_n \), then \( \tilde{\sigma}_1 = w^r \tilde{\sigma}_2 \) for \( r \in \mathbb{Z} \), and hence \( \gamma^r \epsilon_2 d = \epsilon_1 d \). If \( r \neq 0 \), that is, \( \tilde{\sigma}_1 \neq \tilde{\sigma}_2 \) and \( \epsilon_1 \neq \epsilon_2 \), then \( \gamma^r \epsilon_2 \epsilon_1^{-1} \) is a nontrivial element of the stabilizer in \( \Gamma \) of \( \epsilon_1 d \), which is a group of cardinality \( \omega_d \).

Conversely, if \( \tilde{\sigma} e = \epsilon_1 d \) for \( \epsilon_1 \in \mathcal{F}_1 \) and if \( \beta \) is a nontrivial element of the stabilizer
of \( \epsilon_1 d \), we have \( \bar{\sigma}_1 e = \beta \epsilon_1 d \). Write \( \beta \epsilon_1 = \gamma' \epsilon_2 \), \( r \in \mathbb{Z} \), \( \epsilon_2 \in \mathcal{F} \). Then \( \epsilon_1 \neq \epsilon_2 \). Note that if \( n \) is large, then \( \epsilon_2 \) belongs to \( \mathcal{F}_1 \). We obtain \( v^{-r} \sigma_1 e = \epsilon_2 d \). This concludes the proof of part (1).

(2) The proof is exactly the same as that of part (1). Let

\[
\text{path}(v_0, \delta v_0) = d_1 - d_2 + \cdots + d_{s-1} - d_s \in \mathbb{Z}[\mathcal{E}(\mathcal{F})].
\]

(Note that \( s \) is even, since \( \delta \) belongs to \( \Gamma \).) Write \( d_j = \{v_j^e, v_j^o\} \), where \( v_j^e \) is the even vertex of \( d_j \), and \( v_j^o \) is the odd vertex of \( d_j \). Note that we have

\[
v_j^o = v_{j+1}^o \quad \text{for } j = 1, 3, \ldots, s - 1,
\]

\[
v_j^e = v_{j+1}^e \quad \text{for } j = 2, 4, \ldots, s - 2,
\]

\[
v_s^e = \delta v_1^e.
\]

Fix \( z_0 \in \mathcal{H}_p(\mathbb{Q}_p^2) \) such that \( r(z_0) = v_0 \). We may choose elements \( z_j^o \) and \( z_j^e \) in \( \mathcal{H}_p(\mathbb{Q}_p^2) \) such that \( r(z_j^o) = v_j^o \), \( r(z_j^e) = v_j^e \), and

\[
z_j^o = z_{j+1}^o \quad \text{for } j = 1, 3, \ldots, s - 1,
\]

\[
z_j^e = z_{j+1}^e \quad \text{for } j = 2, 4, \ldots, s - 2,
\]

\[
z_1^e = z_0, \quad z_s^e = \delta z_0.
\]

Hence

\[
(\epsilon z_1^o)(\epsilon z_2^o)^{-1} \cdots (\epsilon z_{s-1}^o)(\epsilon z_s^o)^{-1} = 1, \quad (\epsilon z_1^e)(\epsilon z_2^e)^{-1} \cdots (\epsilon z_{s-2}^e)(\epsilon z_{s-1}^e)^{-1} = 1,
\]

so that

\[
\prod_{\epsilon \in \mathcal{F}_1} \epsilon \delta z_0 = \prod_{\epsilon \in \mathcal{F}_1} \left( \frac{\epsilon z_1^o}{\epsilon z_2^o} \right) \left( \frac{\epsilon z_2^o}{\epsilon z_3^o} \right)^{-1} \cdots \left( \frac{\epsilon z_s^o}{\epsilon z_1^o} \right)^{-1}.
\]

Fix a large odd integer \( n \). For each \( 1 \leq j \leq s \), let \( \mathcal{F}(j) \) be the set of elements \( \epsilon \) in \( \mathcal{F}_1 \) such that \( \epsilon d_j \) has level less than or equal to \( n \). Lemma 7.3 shows that the sets \( \mathcal{F}(j) \) are finite. By Lemma 7.1, we have the congruence

\[
(5) \quad \prod_{\epsilon \in \mathcal{F}_1} \epsilon \delta z_0 \equiv \prod_{\epsilon \in \mathcal{F}(1)} \left( \frac{\epsilon z_1^o}{\epsilon z_1^o} \right) \prod_{\epsilon \in \mathcal{F}(2)} \left( \frac{\epsilon z_2^o}{\epsilon z_2^e} \right)^{-1} \cdots \prod_{\epsilon \in \mathcal{F}(s)} \left( \frac{\epsilon z_s^o}{\epsilon z_s^e} \right)^{-1} \pmod{p^n}.
\]

Each of the factors in the right-hand side of equation (5) can be broken up into three contributions:

\[
\prod_{\mathcal{F}(j)} \left( \frac{\epsilon z_j^o}{\epsilon z_j^e} \right) = \prod_{\ell(\epsilon d_j) < n} \epsilon z_j^o \cdot \prod_{\ell(\epsilon d_j) < n} (\epsilon z_j^e)^{-1} \cdot \prod_{\ell(\epsilon d_j) = n} (\epsilon z_j^e)^{\mu_j},
\]

where \( \pi_j = o \) (respectively, \( \pi_j = e \)) if the distance of the furthest vertex of \( \epsilon d_j \) from \( v_0 \) is odd (respectively, even) and where we set \( \mu_j = 1 \) in the first case and \( \mu_j = -1 \)
By Lemma 2.3, the duality \langle G \rangle yields the equality in formula (5). Hence we obtain

\[
\prod_{e \in \mathcal{F}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} = \prod_{\ell(e) = n} (\epsilon z_1)_{\mu_1} \cdot \prod_{\ell(e_2) = n} (\epsilon z_2)^{\mu_2} \cdots \prod_{\ell(e_i) = n} (\epsilon z_i)^{\mu_i} (\mod p^n).
\]

As in the remarks before Lemma 7.6, let \( e \) be an edge of level \( n \) such that its vertex \( v \) of level \( n \) has distance from \( v_0 \) also equal to \( n \). Choose any \( z \in \mathbb{H}_p(\mathbb{Q}_p^2) \) with \( r(z) = v \). Since \( \tilde{G}_n \) acts simply transitively on the set of edges of level \( n \), Lemma 7.1 gives

\[
\prod_{e \in \mathcal{F}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} = \prod_{\tilde{\sigma} \in d_1} (\tilde{\sigma} z)^{\mu_{\tilde{\sigma}}} \cdot \prod_{\tilde{\sigma} \in d_2} (\tilde{\sigma} z)^{-\mu_{\tilde{\sigma}}} \cdots \prod_{\tilde{\sigma} \in d_i} (\tilde{\sigma} z)^{-\mu_{\tilde{\sigma}}} (\mod p^n).
\]

By Lemma 7.6, we obtain

\[
\prod_{e \in \mathcal{F}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} = \prod_{\tilde{\sigma} \in d_1} \tilde{\sigma}^{\mu_{\tilde{\sigma}}} \cdot \prod_{\tilde{\sigma} \in d_2} \tilde{\sigma}^{-\mu_{\tilde{\sigma}}} \cdots \prod_{\tilde{\sigma} \in d_i} \tilde{\sigma}^{-\mu_{\tilde{\sigma}}} (\mod p^n),
\]

where

\[
M = \begin{cases} 
(\text{path}(v_0, \delta v_0), \sum_{e \in G_n} \mu_{\tilde{\sigma}} \sigma e) & \text{if } \iota = 1, \\
(\text{path}(v_0, \delta v_0), \sum_{e \in G_n} (\mu_{\tilde{\sigma}} - \mu_{\tilde{\sigma}} w) \sigma e) & \text{if } \iota = 2.
\end{cases}
\]

By Lemma 2.3, the duality \( \langle , \rangle \) induces a pairing on \( H_1(\mathfrak{g}, \mathbb{Z}) \times \mathcal{M} \). In the case \( \iota = 1 \), one sees directly that \( \sum_{e \in G_n} \mu_{\tilde{\sigma}} \sigma e \) has trivial image in \( \mathcal{M} \), so that \( M \) is zero. Consider now the case \( \iota = 2 \). Since we are interested in computing \( j(c)(\tilde{\delta}) \), we need only consider the image of the homomorphism \( j(c) \) in \( N_{\mathfrak{sp}} \otimes \mathbb{Q}_p \). Thus, we may view the above pairing as being defined on \( H_1(\mathfrak{g}, \mathbb{Z})^- \times \mathcal{M}_{\mathfrak{sp}} \), where \( H_1(\mathfrak{g}, \mathbb{Z})^- \) indicates the “minus” eigenspace for the action of \( w \) on \( H_1(\mathfrak{g}, \mathbb{Z}) \), and we may assume from now on that \( \text{path}(v_0, \delta v_0) \) belongs to \( H_1(\mathfrak{g}, \mathbb{Z})^- \). One checks that the image \( \iota \sum_{e \in G_n} \mu_{\tilde{\sigma}} \sigma e \) in \( \mathcal{M}_{\mathfrak{sp}} \) of the element \( \sum_{e \in G_n} (\mu_{\tilde{\sigma}} - \mu_{\tilde{\sigma}} w) \sigma e \) is trivial, so that also in this case, \( M \) is zero. Hence, in all cases,

\[
\prod_{e \in \mathcal{F}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} = \prod_{\tilde{\sigma} \in d_1} \tilde{\sigma}^{\mu_{\tilde{\sigma}}} \cdot \prod_{\tilde{\sigma} \in d_2} \tilde{\sigma}^{-\mu_{\tilde{\sigma}}} \cdots \prod_{\tilde{\sigma} \in d_i} \tilde{\sigma}^{-\mu_{\tilde{\sigma}}} (\mod p^n).
\]

Let \( \text{rec}_{p,n} : G_\infty \to G_n \) be the composite of the reciprocity map with the natural projection of \( G_\infty \) onto \( G_n \). Suppose that \( \iota = 1 \). By Lemma 7.6, the above relation yields the equality in \( G_n \):

\[
\text{rec}_{p,n} \left( \prod_{e \in \mathcal{F}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} \right) = \prod_{\sigma \in d_1} \sigma^{\omega_{d_1}} \mu_{\tilde{\sigma}} \cdot \prod_{\sigma \in d_2} \sigma^{-\omega_{d_2}} \mu_{\tilde{\sigma}} \cdots \prod_{\sigma \in d_i} \sigma^{-\omega_{d_i}} \mu_{\tilde{\sigma}}.
\]
Recall the derivative $\mathcal{L}'_{p,n}(\mathcal{N}_{sp}/H, P_0) \in \mathcal{N}_{sp} \otimes G_n$ defined in formula (3) at the end of Section 3. By the definition of the bijection $\kappa$ of Lemma 2.2, the right-hand side of the above equality can be written as

$$\mathcal{L}'_{p,n}(\mathcal{N}_{sp}/H, P_0)(\bar{\delta}) = \langle \text{path}(v_0, \delta v_0), \sum_{g \in G_n} e_n(i)^g \otimes g^{-1} \rangle,$$

where, by an abuse of notation, $\sum_{g \in G_n} e_n(i)^g \otimes g^{-1}$ is viewed as an element of $\mathcal{M}_{sp} \otimes G_n$. When $\iota = 2$, a similar computation shows that

$$\mathcal{L}'_{p,n}(\mathcal{N}_{sp}/H, P_0)(\bar{\delta}) = \text{rec}_{p,n}\left( \prod_{\epsilon \in \mathcal{G}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} \right).$$

By passing to the limit, one obtains in all cases

$$\mathcal{L}'_{p}(\mathcal{N}_{sp}/H, P_0)(\bar{\delta}) = \text{rec}_p\left( \prod_{\epsilon \in \mathcal{G}_1} \frac{\epsilon \delta z_0}{\epsilon z_0} \right).$$

In other words, by definition of the map $j$,

$$\mathcal{L}'_{p}(\mathcal{N}_{sp}/H, P_0) = j(\tau),$$

as was to be shown.
