COHOMOLOGICAL DIMENSION AND SCHREIER'S FORMULA IN GALOIS COHOMOLOGY

JOHN LABUTE, NICOLE LEMIRE[†], JÁN MINÁČ[‡], AND JOHN SWALLOW

ABSTRACT. Let p be a prime and F a field containing a primitive pth root of unity. Then for $n \in \mathbb{N}$, the cohomological dimension of the maximal pro-p-quotient G of the absolute Galois group of F is $\leq n$ if and only if the corestriction maps $H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ are surjective for all open subgroups H of index p. Using this result we derive a surprising generalization to $\dim_{\mathbb{F}_p} H^n(H, \mathbb{F}_p)$ of Schreier's formula for $\dim_{\mathbb{F}_p} H^1(H, \mathbb{F}_p)$.

For a prime p, let F(p) denote the maximal p-extension of a field F. One of the fundamental questions in the Galois theory of p-extensions is to discover useful interpretations of the cohomological dimension cd(G) of the Galois group G = Gal(F(p)/F) in terms of the arithmetic of p-extensions of F. When cd(G) = 1, for instance, we know that G is a free pro-p-group [S1, §3.4], and when cd(G) = 2 we have important information on the G-module of relations in a minimal presentation [K, §7.3].

For a fixed n > 2, however, little is known about the structure of p-extensions when cd(G) = n. Now when n = 1 and G is finitely generated as a pro-p-group, we have Schreier's well-known formula

(1)
$$h_1(H) = 1 + [G:H](h_1(G) - 1)$$

for each open subgroup H of G, where

$$h_1(H) := \dim_{\mathbb{F}_p} H^1(H, \mathbb{F}_p).$$

(See, for instance, [K, Example 6.3].)

Observe that from basic properties of p-groups it follows that for each open subgroup H of G there exists a chain of subgroups

$$G = G_0 \supset G_1 \supset \cdots \supset G_k = H$$

such that G_{i+1} is normal in G_i and $[G_i : G_{i+1}] = p$ for each $i = 0, 1, \ldots, k-1$. Since closed subgroups of free pro-p-groups are free [S1, Corollary 3, §I.4.2], Schreier's formula (1) is equivalent to the seemingly weaker statement that the formula holds for all open subgroups H of G of index p:

(2)
$$h_1(H) = 1 + p(h_1(G) - 1).$$

Using the Bloch-Kato Conjecture (see [V1], [V2], [Su], and [R]), we deduce a remarkable generalization of Schreier's formula for each $n \in \mathbb{N}$, as follows. Let F^{\times} denote the nonzero elements of a field F, and for $c \in F^{\times}$, let $(c) \in H^1(G, \mathbb{F}_p)$ denote the corresponding class. For $\alpha \in H^m(G, \mathbb{F}_p)$ abbreviate by $\operatorname{ann}_n \alpha$ the annihilator

$$\operatorname{ann}_n \alpha = \{ \beta \in H^n(G, \mathbb{F}_p) \mid \alpha \cup \beta = 0 \}.$$

Finally, set $h_n(G) = \dim_{\mathbb{F}_p} H^n(G, \mathbb{F}_p)$. Observe that the hypothesis on the surjectivity of the corestriction on degree n cohomology holds for all pro-p-groups of cohomological dimension n [NSW, Proposition 3.3.8]; conversely, in section 1, we show that this hypothesis for all subgroups of index p implies $cd(G) \leq n$.

We denote by ξ_p a pth root of unity of order p.

Theorem 1. Suppose that $\xi_p \in F$, cd(G) = n, and $h_n(G) < \infty$. Let H be an open subgroup of G of index p, with fixed field $F(\sqrt[p]{a})$, and suppose that the corestriction map $H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective. Then

$$h_n(H) = a_{n-1}(G, H) + p(h_n(G) - a_{n-1}(G, H)),$$

where $a_{n-1}(G, H)$ is the codimension of $\operatorname{ann}_{n-1}(a)$:

$$a_{n-1}(G,H) := \dim_{\mathbb{F}_p} \left(H^{n-1}(G,\mathbb{F}_p) / \operatorname{ann}_{n-1}(a) \right).$$

The proof of Theorem 1 brings additional insight into the structure of Schreier's formula; in fact, it makes Schreier's formula transparent for any $n \in \mathbb{N}$. In section 1, we derive several interpretations for the statement cd(G) = n. First, we prove in Theorem 2 that if F contains a primitive pth root of unity ξ_p then $cd(G) \leq n$ if and only if the corestriction maps $cor : H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ are surjective for all open subgroups H of G of index p. As a corollary, we show that the

corresponding cohomology groups $H^{n+1}(H, \mathbb{F}_p)$ are all free as $\mathbb{F}_p[G/H]$ -modules if and only if $\operatorname{cd}(G) \leq n$, under the additional hypothesis that $F = F^2 + F^2$ when p = 2. Finally, we show in Theorem 3 that if G is finitely generated, then $\operatorname{cd}(G) \leq n$ if and only if a single corestriction map, from the Frattini subgroup $\Phi(G) = G^p[G, G]$ of G, is surjective. In section 2 we prove Theorem 1.

For basic facts about Galois cohomology and maximal p-extensions of fields, we refer to [K] and [S1]. In particular, we work in the category of pro-p-groups.

1. When is
$$cd(G) = n$$
?

¿From the Bloch-Kato Conjecture ([V1], [V2], [Su], and [R]), we have the following interesting translation of the statement $cd(G) \leq n$ for a given $n \in \mathbb{N}$. Observe that when $cd(G) \leq n$, the corestriction maps $cor : H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ are surjective for all open subgroups H of G of index p [NSW, Proposition 3.3.8].

Theorem 2. Suppose that $\xi_p \in F$. Then for each $n \in \mathbb{N}$ we have $cd(G) \leq n$ if and only if

$$\operatorname{cor}: H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$$

is surjective for every open subgroup H of G of index p.

Proof. Suppose that F satisfies the conditions of the theorem, and let $G_{F(p)}$ be the absolute Galois group of F(p).

Observe that since F contains ξ_p , the maximal p-extension F(p) is closed under taking pth roots and hence $H^1(G_{F(p)}, \mathbb{F}_p) = \{0\}$. By the Bloch-Kato Conjecture [V2, Theorem 7.1], the subring of the cohomology ring $H^*(G_{F(p)}, \mathbb{F}_p)$ consisting of elements of positive degree is generated by cup-products of elements in $H^1(G_{F(p)}, \mathbb{F}_p)$. Hence $H^n(G_{F(p)}, \mathbb{F}_p) = \{0\}$ for $n \in \mathbb{N}$. Then, considering the Lyndon-Hochschild-Serre spectral sequence associated to the exact sequence

$$1 \to G_{F(p)} \to G_F \to G \to 1$$
,

we have that

(3)
$$\inf: H^{\star}(G, \mathbb{F}_p) \to H^{\star}(G_F, \mathbb{F}_p)$$

is an isomorphism.

Now suppose that cor : $H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective for all open subgroups H of G of index p. Let K be the fixed field of such a subgroup H. Then $K = F(\sqrt[p]{a})$ for some $a \in F^{\times}$. From [V1, Lemma 6.11 and §7] and [V2, §6 and Theorem 7.1], as well as [V1, Proposition 5.2], modified in [LMS1, Theorem 5] and translated to G from G_F via the inflation maps (3) above, we obtain the following exact sequence:

$$(4) \quad H^n(H,\mathbb{F}_p) \xrightarrow{\operatorname{cor}} H^n(G,\mathbb{F}_p) \xrightarrow{-\cup (a)} H^{n+1}(G,\mathbb{F}_p) \xrightarrow{\operatorname{res}} H^{n+1}(H,\mathbb{F}_p).$$

Therefore res : $H^{n+1}(G, \mathbb{F}_p) \to H^{n+1}(H, \mathbb{F}_p)$ is injective for every open subgroup H of G of index p.

Now consider an arbitrary element

$$\alpha = (a_1) \cup \cdots \cup (a_{n+1}) \in H^{n+1}(G, \mathbb{F}_p),$$

where $a_i \in F^{\times}$ and (a_i) is the element of $H^1(G, \mathbb{F}_p)$ associated to a_i , $i=1,2,\ldots,n+1$. Suppose that $(a_1) \neq 0$, and set $K=F(\sqrt[p]{a_1})$ and $H=\operatorname{Gal}(F(p)/K)$. We have $0=\operatorname{res}(\alpha) \in H^{n+1}(H,\mathbb{F}_p)$. Since res is injective, $\alpha=0$. Again by the Bloch-Kato conjecture [V1, Theorem 7.1], we know that $H^{n+1}(G,\mathbb{F}_p)$ is generated by the elements α above. Hence $H^{n+1}(G,\mathbb{F}_p)=\{0\}$ and therefore $\operatorname{cd}(G) \leq n$. (See [K, page 49].)

Conversely, if $\operatorname{cd}(G) \leq n$ then by [NSW, Proposition 3.3.8] we conclude that $\operatorname{cor}: H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective for open subgroups H of G of index p.

Using conditions obtained in [LMS2] for $H^n(H, \mathbb{F}_p)$ to be a free $\mathbb{F}_p[G/H]$ -module, we obtain the following corollary. We observe the convention that $\{0\}$ is a free $\mathbb{F}_p[G/H]$ -module.

Corollary. Suppose that $\xi_p \in F$ and if p = 2 suppose also that $F = F^2 + F^2$. Then for each $n \in \mathbb{N}$, we have that $H^{n+1}(H, \mathbb{F}_p)$ is a free $\mathbb{F}_p[G/H]$ -module for every open subgroup H of G of index p if and only if $\operatorname{cd}(G) \leq n$.

Observe that the condition $F = F^2 + F^2$ is satisfied in particular when F contains a primitive fourth root of unity i: for all $c \in F^{\times}$, $c = ((c+1)/2)^2 + ((c-1)i/2)^2$.

Proof. Assume that F is as above, $n \in \mathbb{N}$, and that $H^{n+1}(H, \mathbb{F}_p)$ is a free $\mathbb{F}_p[G/H]$ -module for every open subgroup H of G of index p. If

p > 2, then it follows from [LMS2, Theorem 1] that the corestriction maps cor : $H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ are surjective for all such subgroups H.

If p=2, then we consider open subgroups H of index 2 with corresponding fixed fields $K=F(\sqrt{a})$. From [LMS2, Theorem 1] we obtain that $\operatorname{ann}_n(a)=\operatorname{ann}_n\left((a)\cup(-1)\right)$. It follows from the hypothesis $F=F^2+F^2$ that $(c)\cup(-1)=0\in H^2(G,\mathbb{F}_2)$ for each $c\in F^\times$ and in particular for c=a. Hence $\operatorname{ann}_n(a)=H^n(G,\mathbb{F}_2)$. But then from exact sequence (4) above, we deduce that $\operatorname{cor}:H^n(H,\mathbb{F}_2)\to H^n(G,\mathbb{F}_2)$ is surjective.

Since our analysis holds for all open subgroups H of index p, by Theorem 2 we conclude that $\operatorname{cd}(G) \leq n$.

Assume now that $\operatorname{cd}(G) \leq n$. Then by Serre's theorem in [S2] we find that $\operatorname{cd}(H) \leq n$ for every open subgroup H of G. Hence $H^{n+1}(H, \mathbb{F}_p) = \{0\}$ which, by our convention, is a free $\mathbb{F}_p[G/H]$ -module, as required.

Remark. When p=2 and $F \neq F^2+F^2$, the statement of the corollary may fail. Consider the case $F=\mathbb{R}$. Then the only subgroup H of index 2 in $G=\mathbb{Z}/2\mathbb{Z}$ is $H=\{1\}$. Then for all $n\in\mathbb{N},\ H^{n+1}(H,\mathbb{F}_2)=\{0\}$ and is free as an $\mathbb{F}_2[G/H]$ -module. However, $\operatorname{cd}(G)=\infty$.

Under the additional assumption that G is finitely generated, we show that the surjectivity of a single corestriction map is equivalent to $cd(G) \leq n$.

Theorem 3. Suppose that $\xi_p \in F$ and G is finitely generated. Then for each $n \in \mathbb{N}$ we have $\operatorname{cd}(G) \leq n$ if and only if

$$\mathrm{cor}: H^n(\Phi(G),\mathbb{F}_p) \to H^n(G,\mathbb{F}_p)$$

is surjective.

Proof. Because G is finitely generated, the index $[G:\Phi(G)]$ is finite, and we may consider a suitable chain of open subgroups

$$G = G_0 \supset G_1 \supset \cdots \supset G_k = \Phi(G)$$

such that $[G_i: G_{i+1}] = p$ for each i = 0, 1, ..., k-1.

By Serre's theorem in [S2], $\operatorname{cd}(H) = \operatorname{cd}(G)$ for every open subgroup H of G. Hence if $\operatorname{cd}(G) \leq n$ we may iteratively apply Theorem 2 to

the chain of open subgroups to conclude that

$$\operatorname{cor}: H^n(\Phi(G), \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$$

is surjective.

Assume now that cor : $H^n(\Phi(G), \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective. For each open subgroup H of G of index p we have a commutative diagram of corestriction maps

since $\Phi(G) \subset H$. We obtain that cor : $H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective, and by Theorem 2 we deduce that $cd(G) \leq n$, as required.

2. Schreier's Formula for H^n

We now prove Theorem 1. Suppose that H is an open subgroup of G of index p and the corestriction map $\operatorname{cor}: H^n(H, \mathbb{F}_p) \to H^n(G, \mathbb{F}_p)$ is surjective. Let $K = F(\sqrt[p]{a})$ be the fixed field of H.

We claim that $\operatorname{ann}_{n-1}\left((a)\cup(\xi_p)\right)=H^{n-1}(G,\mathbb{F}_p)$. Suppose that $\alpha\in H^{n-1}(G,\mathbb{F}_p)$. By the surjectivity hypothesis there exists $\beta\in H^n(H,\mathbb{F}_p)$ such that $\operatorname{cor}\beta=(\xi_p)\cup\alpha$. From [V1, Proposition 5.2] modified in [LMS1, Theorem 5], $(a)\cup(\operatorname{cor}\beta)=0$ and hence $(a)\cup(\xi_p)\cup\alpha=0$. Therefore the claim is established. By [LMS1, Theorem 1], we obtain the decomposition

$$H^n(H, \mathbb{F}_p) = X \oplus Y,$$

where X is a trivial $\mathbb{F}_p[G/H]$ -module and Y is a free $\mathbb{F}_p[G/H]$ -module. (Because $\operatorname{ann}_{n-1}((a) \cup (\xi_p)) = H^{n-1}(G, \mathbb{F}_p)$ there are no 2-dimensional summands, and by the surjectivity of the corestriction map, the fourth summand Z in [LMS1], a trivial $\mathbb{F}_p[G/H]$ -module, is also $\{0\}$.) Moreover

$$x := \dim_{\mathbb{F}_p} X = \dim_{\mathbb{F}_p} H^{n-1}(G, \mathbb{F}_p) / \operatorname{ann}_{n-1}(a) = a_{n-1}(G, H), \text{ and}$$

 $y := \operatorname{rank} Y = \dim_{\mathbb{F}_p} H^n(G, \mathbb{F}_p) / (a) \cup H^{n-1}(G, \mathbb{F}_p).$

Therefore $h_n(H) = \dim_{\mathbb{F}_p} H^n(H, \mathbb{F}_p) = x + py$.

Now, considering the exact sequence

$$0 \to \frac{H^{n-1}(G, \mathbb{F}_p)}{\operatorname{ann}_{n-1}(a)} \xrightarrow{-\cup (a)} H^n(G, \mathbb{F}_p) \to \frac{H^n(G, \mathbb{F}_p)}{(a) \cup H^{n-1}(G, \mathbb{F}_p)} \to 0,$$

we see that $\dim_{\mathbb{F}_p} H^n(H, \mathbb{F}_p)$ is equal to the sum of the dimension x of the kernel and p times the dimension y of the cokernel, and the theorem follows.

Observe that our formula $h_n(H) = x + py$ holds without the assumption that $h_n(G)$ is finite. (This assumption is used only in the formulation of Theorem 1 where we subtract $a_{n-1}(G, H)$ from $h_n(G)$.)

When n = 1, $\operatorname{ann}_{n-1}(a) = \{0\}$ so that $a_{n-1}(G, H) = 1$. Therefore when G is finitely generated we recover Schreier's formula (2):

$$h_1(H) = 1 + p(h_1(G) - 1).$$
