

MATH 598: TOPICS IN STATISTICS

METROPOLIS-HASTINGS FOR CONTINUOUS STATE SPACES

We wish to sample from the $\text{Gamma}(\gamma, 1)$ distribution

$$\pi(x) = \frac{1}{\Gamma(\gamma)} x^{\gamma-1} e^{-x} \quad x > 0$$

using the Metropolis-Hastings algorithm. To implement the algorithm we need to

1. pick a starting value x_0
2. for steps $t = 0, 1, 2, \dots, N, \dots$

(i) propose a new value z from some transition density $q(x_t, z)$, some conditional density given x_t ,

(ii) set $x_{t+1} = z$ with probability

$$\alpha(x_t, z) = \min \left\{ 1, \frac{\pi(z)q(z, x_t)}{\pi(x_t)q(x_t, z)} \right\}$$

otherwise set $x_{t+1} = x_t$.

The selected transition density should leave the resulting chain irreducible, aperiodic and positive recurrent, so that $\pi(x)$ is the stationary distribution of the chain. It is sufficient to achieve a $q(x, z)$ that proposes values on the support of $\pi(x)$. In the algorithms below, the proposal that sets

$$z = |x + \delta| \quad \delta \sim \text{Normal}(0, \sigma_\gamma^2)$$

for some $\sigma_\gamma > 0$ is used. With this choice it follows that $q(x, z) = q(z, x)$, and

$$\alpha(x, z) = \min \left\{ 1, \frac{\pi(z)}{\pi(x)} \right\}.$$

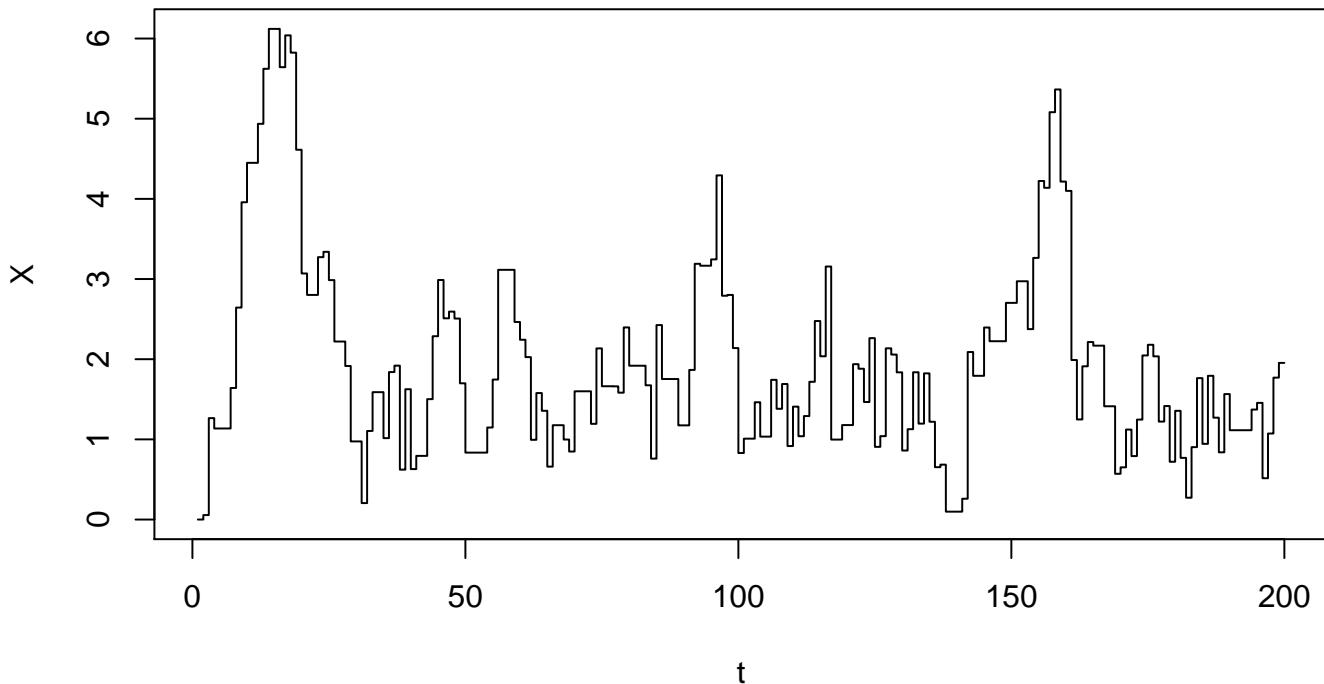

Different results are obtained for different settings. Performance can be assessed using

- trace plots of sampled $\{x_t\}$;
- the autocorrelation function (acf) of the sampled values;
- the computed effective sample size (ESS).

In these examples, $\gamma = 2.5$. First, a run starting from $x_0 = 0$ with $\sigma_\gamma = 1$.

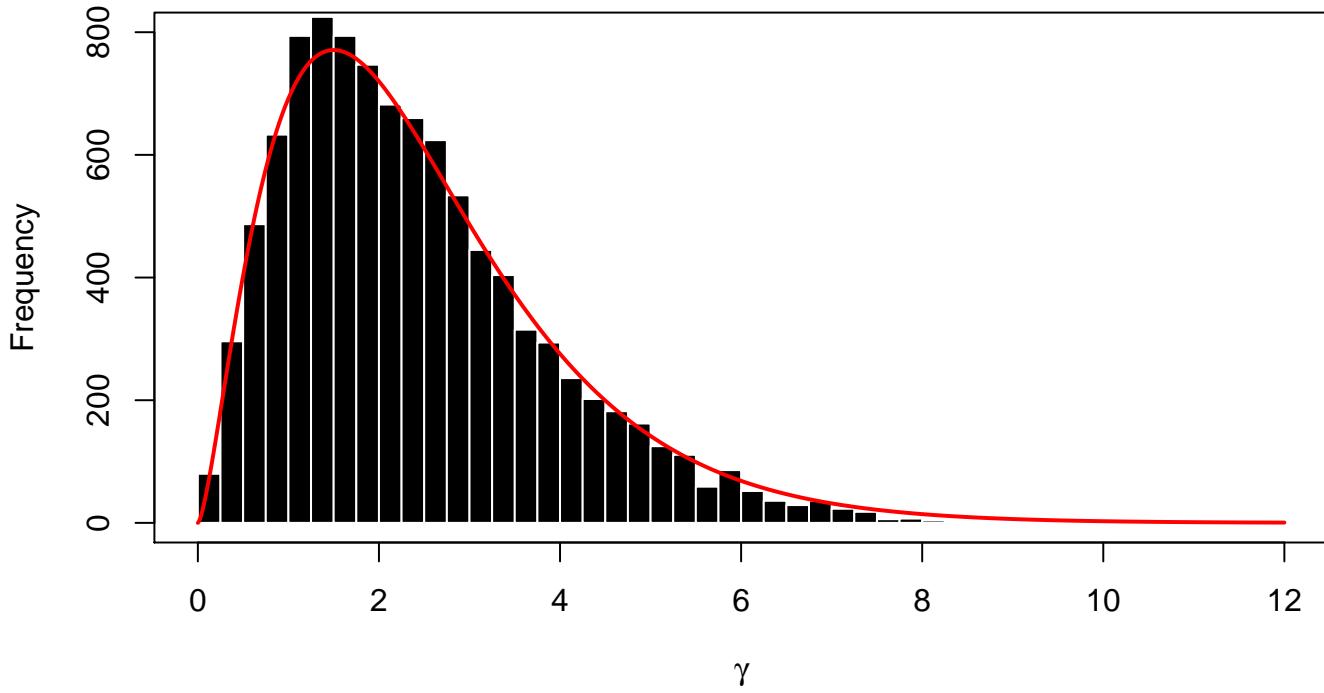

```
set.seed(4532)
N<-10000
gam<-2.5
sigg<-1
X<-rep(0,N)
X[1]<-0
for(istep in 2:N){
  x<-X[istep-1]
  Z<-abs(rnorm(1,x,sigg))
  al<-min(1,dgamma(Z,gam)/dgamma(x,gam))
  u<-runif(1)
  if(u < al){
    X[istep]<-Z
  }else{
    X[istep]<-x
  }
}
par(mar=c(4,4,2,0))
plot(X[1:200],type="s",xlab="t",ylab="X",main='Trace plot')
```

Trace plot

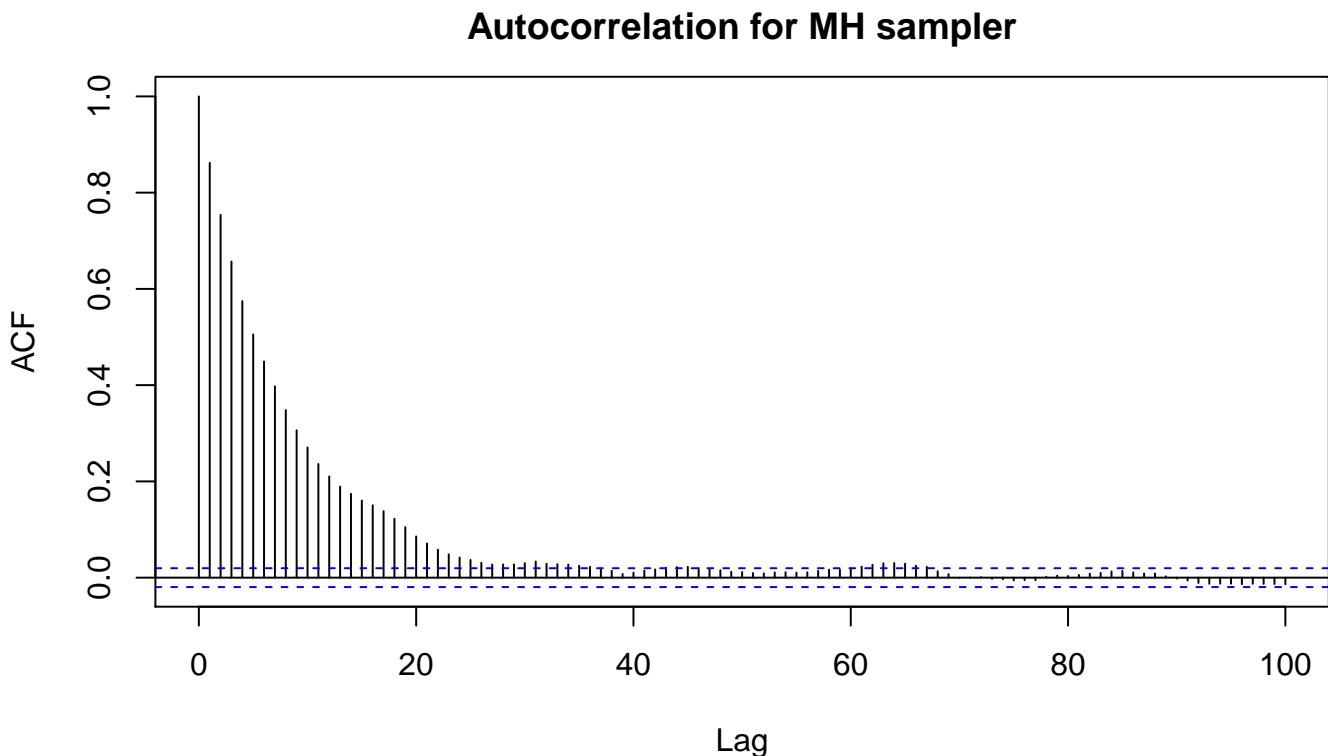

```
par(mar=c(4,4,2,0))
hist(X,br=seq(0,12,by=0.25),xlab=expression(gamma),main="Histogram of sampled values",
  col="black",border="white",ylim=range(0,800));box()
xv<-seq(0,12,by=0.01);yv<-dgamma(xv,gam);lines(xv,yv*N*0.25,col="red",lwd=2)
```

Histogram of sampled values

```
par(mar=c(4,4,2,0))
acf(X,lag.max=100,main=' ');title("Autocorrelation for MH sampler",line=1)
```

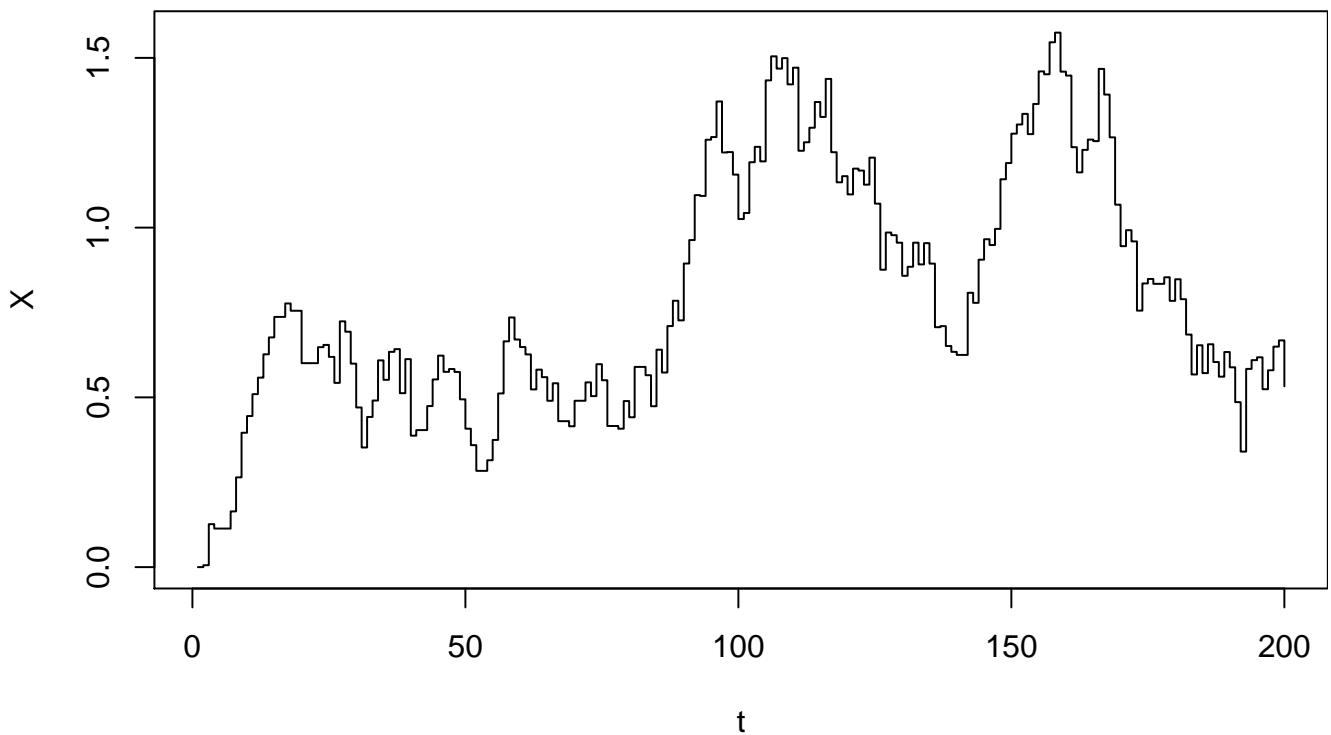

```
library(coda)
effectiveSize(X)

+      var1
+ 681.3151
```

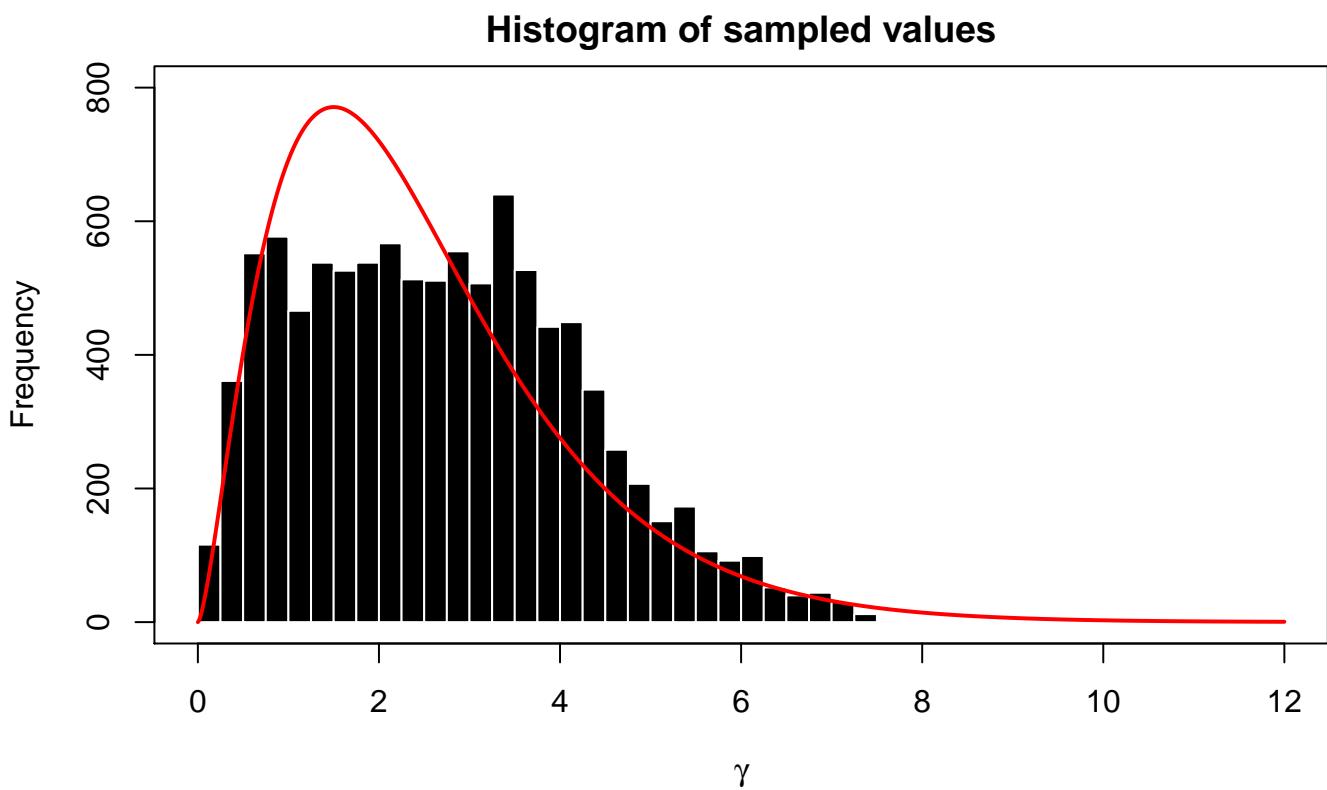

Here the effective sample size is 681.315096, which is quite low given the run length. We now run the algorithm again with $\sigma_\gamma = 0.1$

```
set.seed(4532)
N<-10000
gam<-2.5
sigg<-0.1
X<-rep(0,N)
X[1]<-0
for(istep in 2:N){
  x<-X[istep-1]
  Z<-abs(rnorm(1,x,sigg))
  al<-min(1,dgamma(Z,gam)/dgamma(x,gam))
  u<-runif(1)
  if(u < al){
    X[istep]<-Z
  }else{
    X[istep]<-x
  }
}
par(mar=c(4,4,2,0))
plot(X[1:200],type="s",xlab="t",ylab="X",main='Trace plot')
```

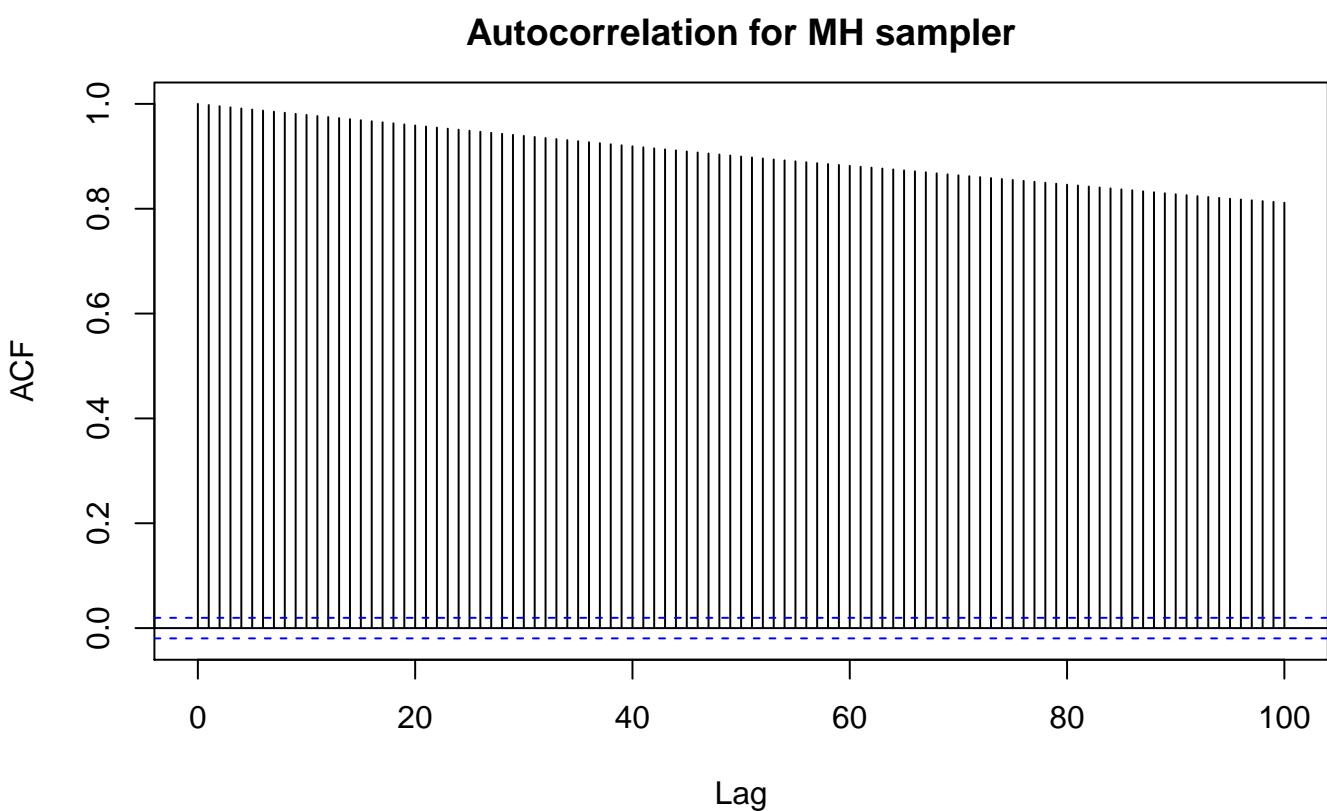

Trace plot

```
par(mar=c(4,4,2,0))
hist(X,br=seq(0,12,by=0.25),xlab=expression(gamma),main="Histogram of sampled values",
  col="black",border="white",ylim=range(0,800));box()
xv<-seq(0,12,by=0.01);yv<-dgamma(xv,gam)
lines(xv,yv*N*0.25,col="red",lwd=2)
```

```
par(mar=c(4,4,2,0))
acf(X,lag.max=100,main=' ');title("Autocorrelation for MH sampler",line=1)
```

```

library(coda)
effectiveSize(X)

+      var1
+ 11.16783

```

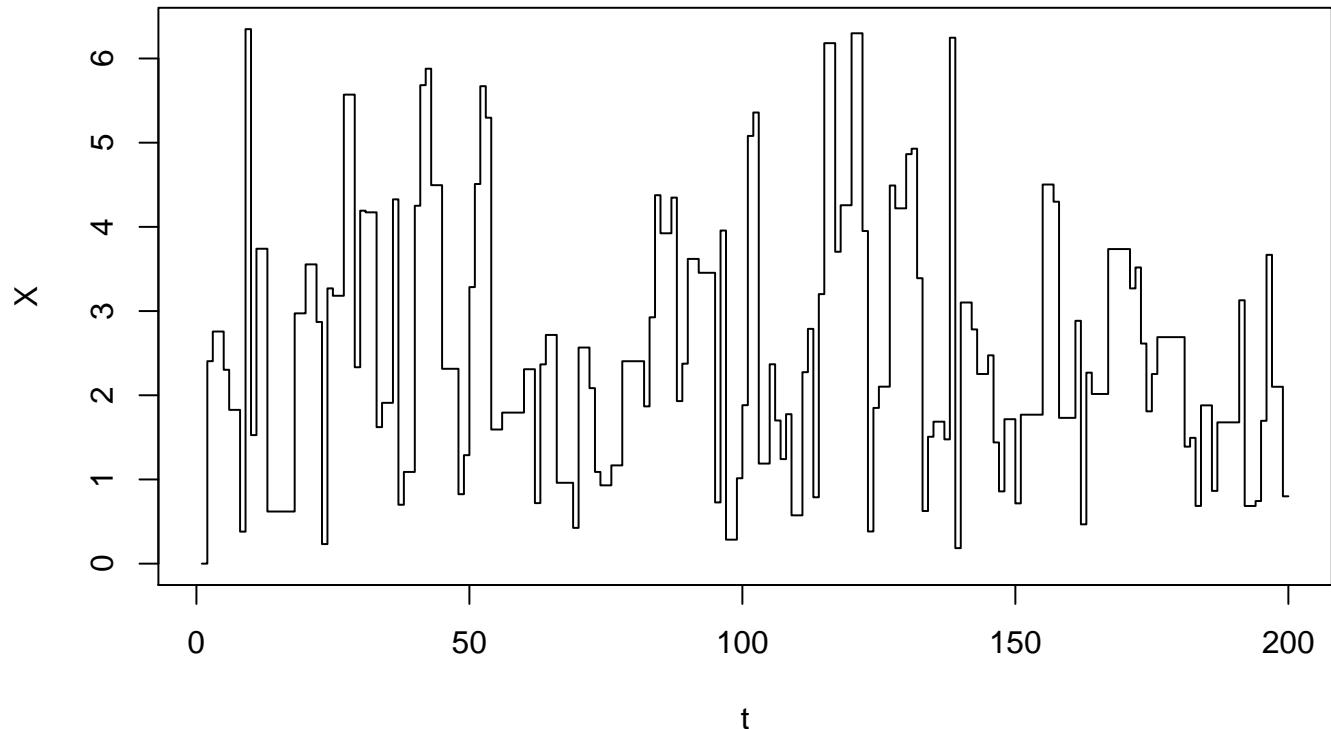

Here the effective sample size is 11.167829, which is extremely poor. Now with $\sigma_\gamma = 3$.

```

set.seed(48532)
N<-10000
gam<-2.5; sigg<-3
X<-rep(0,N);X[1]<-0
for(istep in 2:N){
  x<-X[istep-1]
  Z<-abs(rnorm(1,x,sigg))
  al<-min(1,dgamma(Z,gam)/dgamma(x,gam))
  u<-runif(1)
  if(u < al){
    X[istep]<-Z
  }else{
    X[istep]<-x
  }
}
par(mar=c(4,4,2,0))
plot(X[1:200],type="s",xlab="t",ylab="X",main='Trace plot')

```

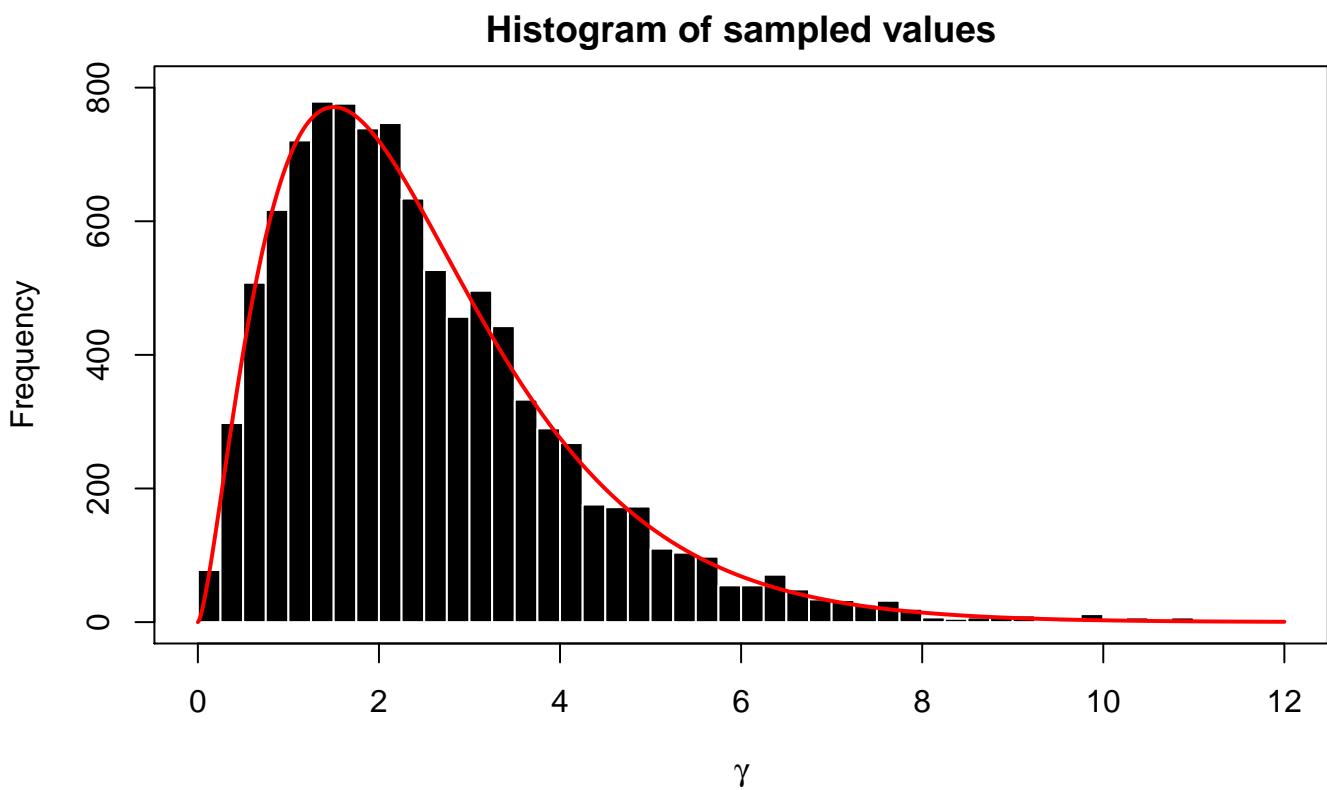

Trace plot

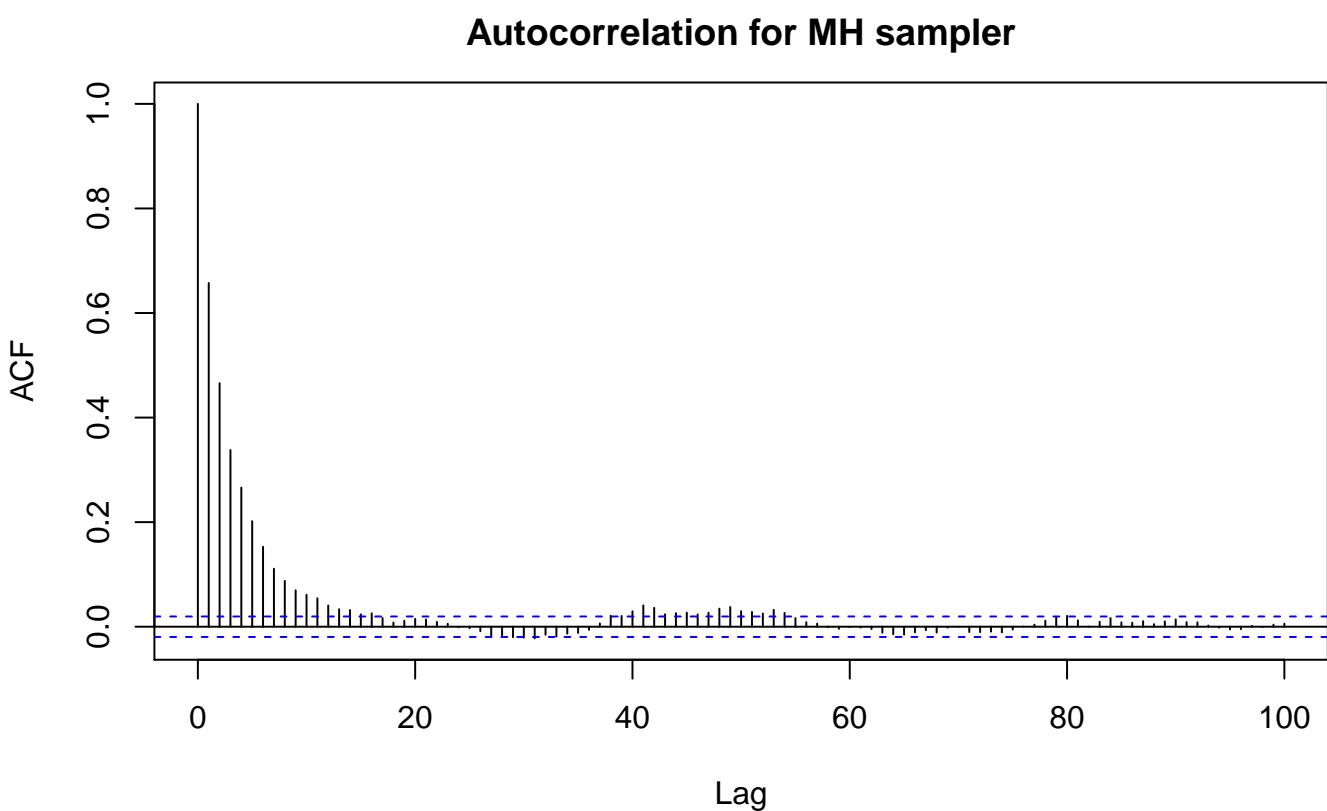

```

par(mar=c(4,4,2,0))
hist(X,br=seq(0,12,by=0.25),xlab=expression(gamma),main="Histogram of sampled values",
  col="black",border="white",ylim=range(0,800));box()
xv<-seq(0,12,by=0.01);yv<-dgamma(xv,gam)
lines(xv,yv*N*0.25,col="red",lwd=2)

```

```
par(mar=c(4,4,2,0))
acf(X,lag.max=100,main=' ');title("Autocorrelation for MH sampler",line=1)
```

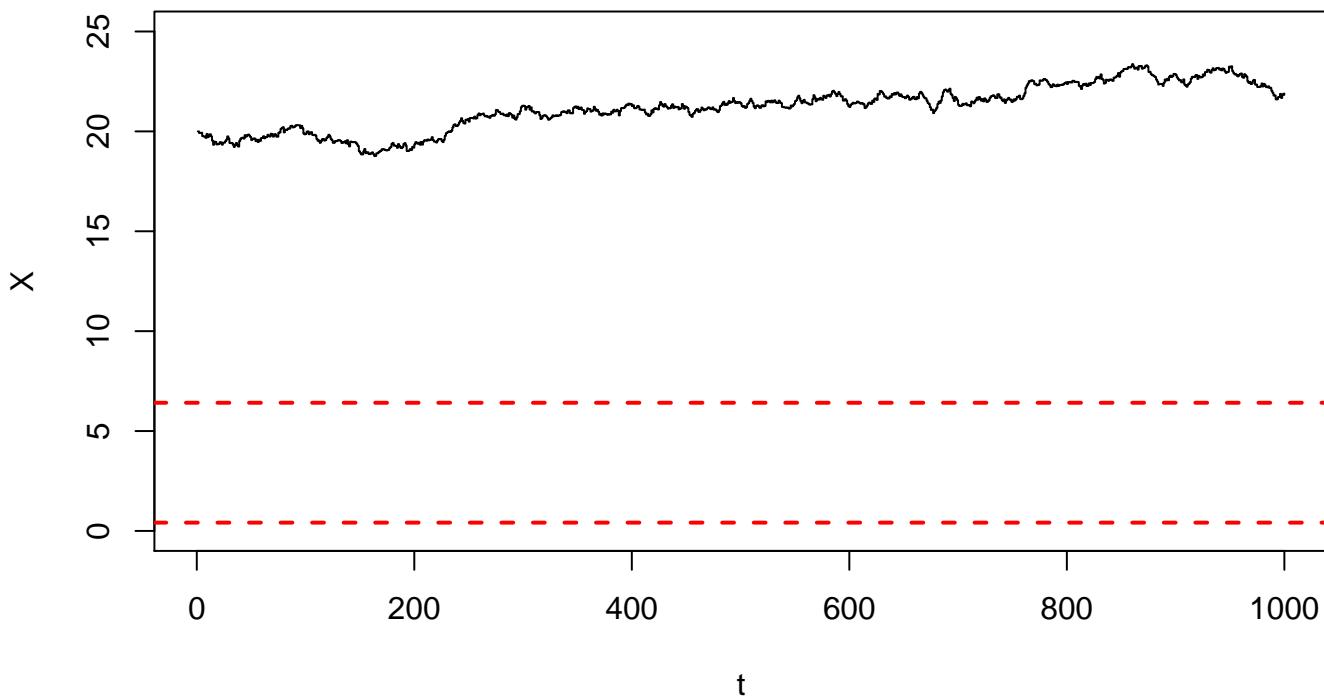

```
effectiveSize(X)
+
  var1
+ 1628.553
```

Here the effective sample size is 1628.552511, which is much better.

Finally we start the chain with $x_0 = 20$, and use $\sigma_\gamma = 0.1$. In the plots, the central 0.95 high probability region of the target distribution is marked by the horizontal red lines; the chain should stabilize to spend 95% of the time in that region.

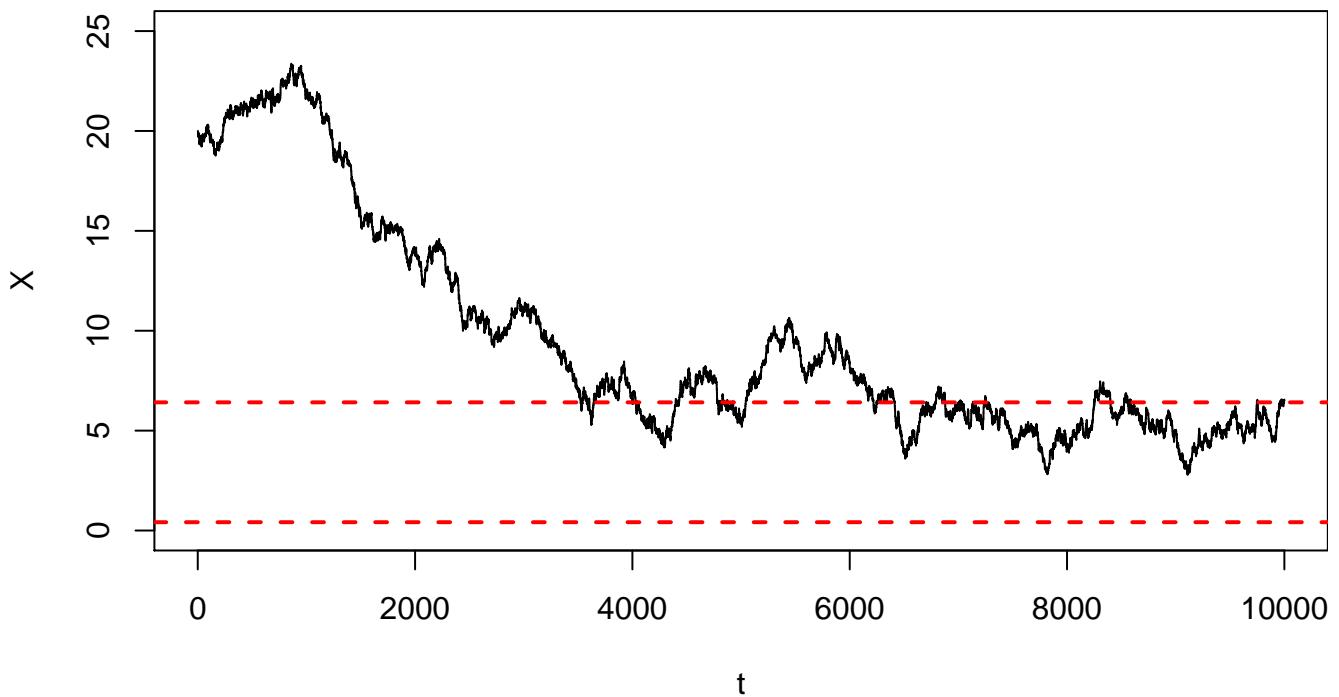

```
set.seed(48532)
N<-20000
gam<-2.5; sigg<-0.1
X<-rep(0,N);X[1]<-20
for(istep in 2:N){
  x<-X[istep-1]
  Z<-abs(rnorm(1,x,sigg))
  al<-min(1,dgamma(Z,gam)/dgamma(x,gam))
  u<-runif(1)
  if(u < al){
    X[istep]<-Z
  }else{
    X[istep]<-x
  }
}
par(mar=c(4,4,3,0))
plot(X[1:1000],type="s",xlab="t",ylab="X",ylim=range(0,25),main='First 1000 iterations')
abline(h=qgamma(c(0.025,0.975),gam),lty=2,lwd=2,col="red")
```

First 1000 iterations

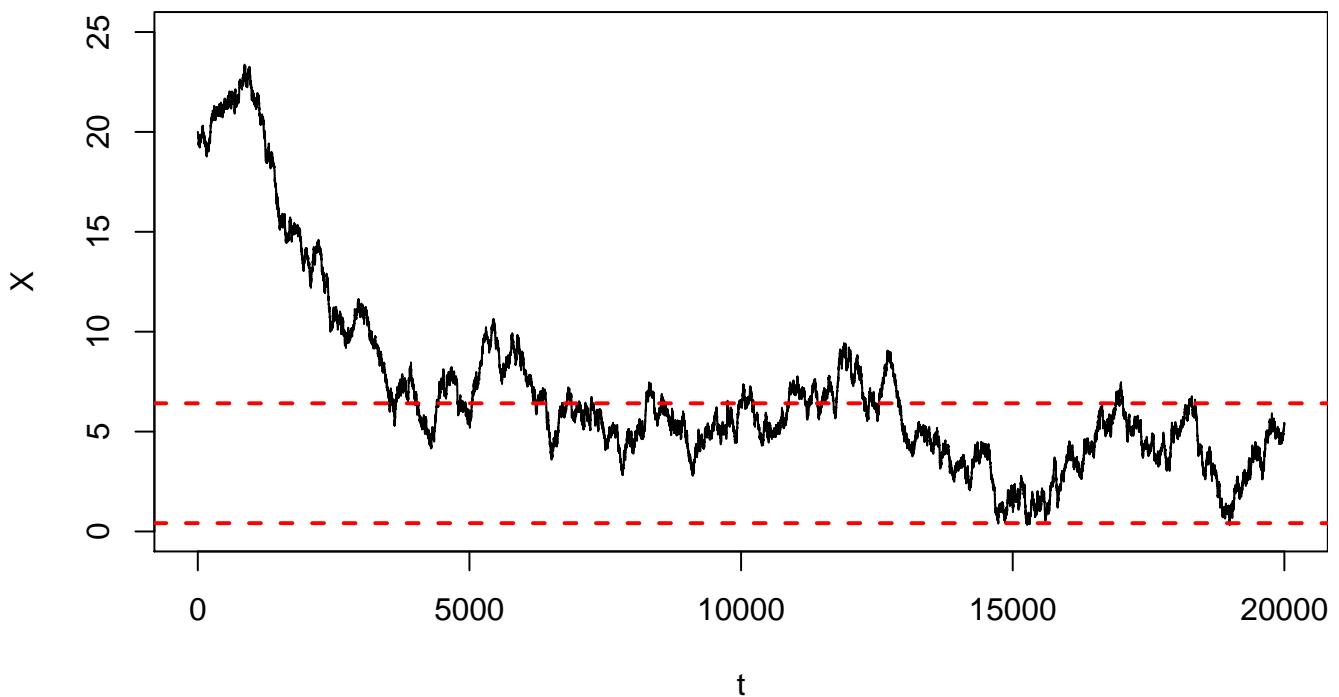

```
par(mar=c(4,4,3,0))
plot(X[1:10000],type="s",xlab="t",ylab="X",ylim=range(0,25),main='First 10000 iterations')
abline(h=qgamma(c(0.025,0.975),gam),lty=2,lwd=2,col="red")
```

First 10000 iterations

```
par(mar=c(4,4,3,0))
plot(X[1:N], type="s", xlab="t", ylab="X", ylim=range(0,25), main='First 20000 iterations')
abline(h=qgamma(c(0.025,0.975),gam), lty=2, lwd=2, col="red")
```

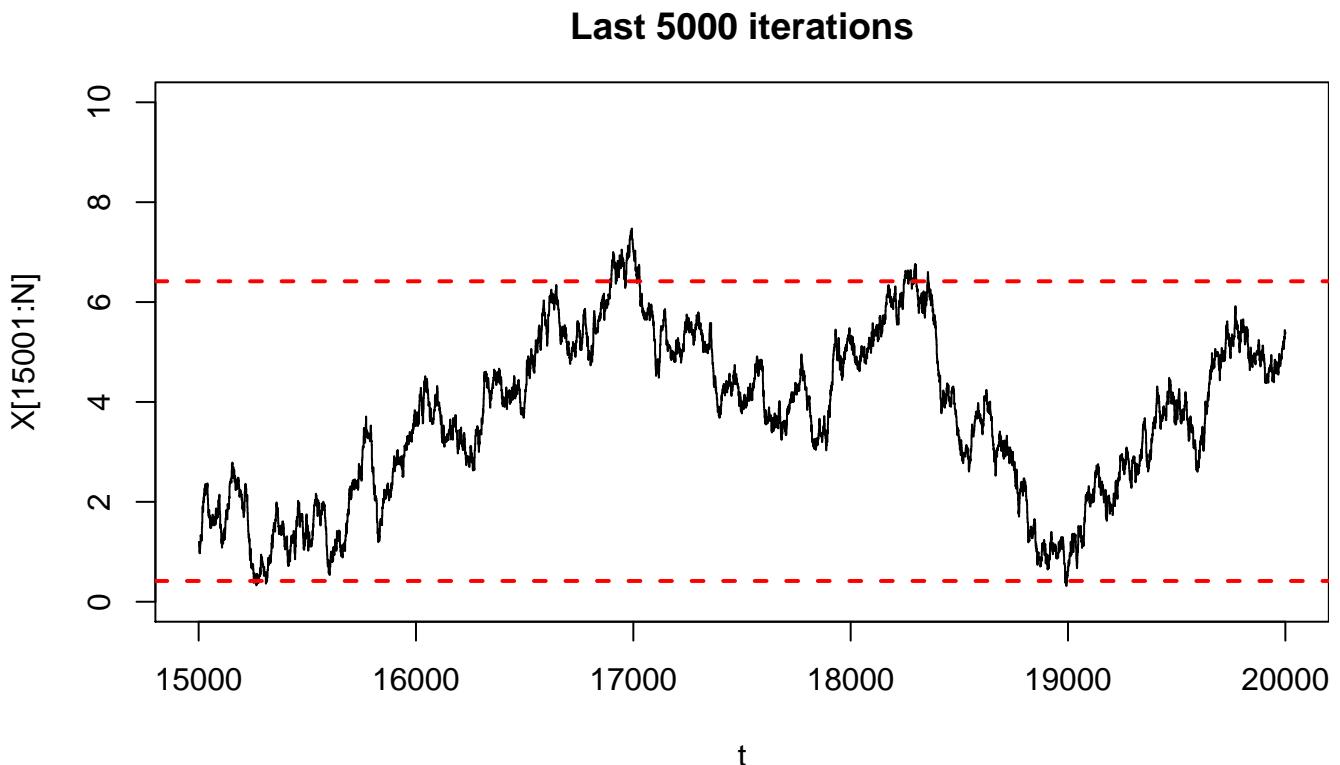

First 20000 iterations

```

par(mar=c(4,4,3,0))
plot(15001:N,X[15001:N],type="s",xlab="t",ylim=range(0,10),main='Last 5000 iterations')
abline(h=qgamma(c(0.025,0.975),gam),lty=2,lwd=2,col="red")

```

Eventually, the chain recovers from the extreme starting value. To regard the collected sample as a correlated sample from the target, we should discard the initial iterations. However, the effective sample sizes are very low due to the high sample autocorrelation in the sampled values.

```

effectiveSize(X[1:1000]) #out of 1000
+
+      var1
+ 2.270879

effectiveSize(X[1:10000]) #out of 10000
+
+      var1
+ 1.802546

effectiveSize(X[1:N])      #out of 20000
+
+      var1
+ 3.918719

effectiveSize(X[15001:N]) #out of 5000
+
+      var1
+ 5.430604

```
